

### Modelling Transport of Volcanic Emissions from Iceland to the UK

#### Paul Agnew and Lucy Davis

Air Quality Seminar, Imperial College 14th July 2010

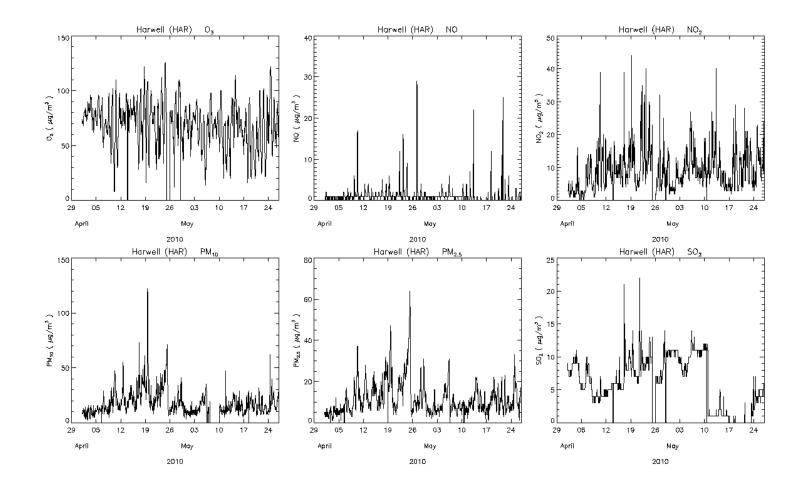

© Crown copyright Met Office

- General features of the eruption
- Monitoring PM and SO2
- Focus on SO2
  - Estimated emissions
  - Modelling transport and dispersion
  - Modelling scenarios
- Acknowledgements: Jim Haywood, Chilbolton
  Observatory / Rutherford Appleton Lab

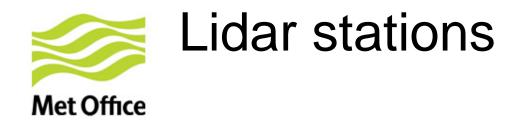

### AURN Measurements at Harwell

### AURN: Leamington Spa

Leamington Spa (LEAM) Learnington Spa (LEAM) 0, NO Learnington Spa (LEAM) NO2 BO. 0a (µ44/m³) NO<sub>2</sub> { µg/m<sup>3</sup> **с**ш/бяГ) ОN 60 H ٥Ľ n | April April May April Мау May Leamington Spa (LEAM) PM<sub>10</sub> Learnington Spa (LEAM) PM<sub>2.5</sub> Leamington Spa (LEAM)  $SO_2$ 41 ( s<sup>u</sup>/бл ) <sup>01</sup>МЧ РМ<sub>215</sub> ( дад/m<sup>3</sup> ) В °m/6π 40 20<sup>3</sup> ( οl April May April May April May 

 15<sup>th</sup> April: 6 lidar stations mobilised with the help of the NERC community

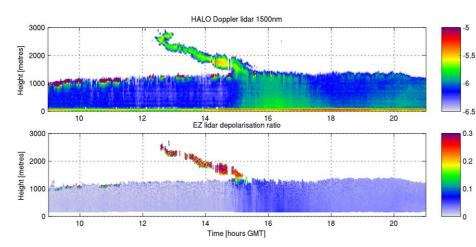

BL mixing processes: 16<sup>th</sup> April

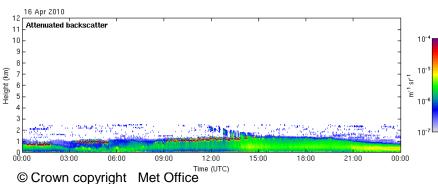

#### Met Office

• Ash "descends" into BL...

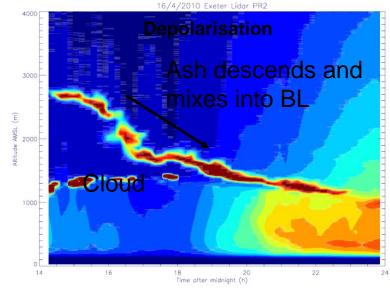

#### Chilbolton (Judith Agnew): mixing at 15.00 UTC

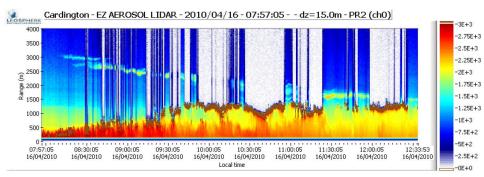

Reading: mixing at 14.00 UTC

#### Exeter: mixing at 19.00 UTC

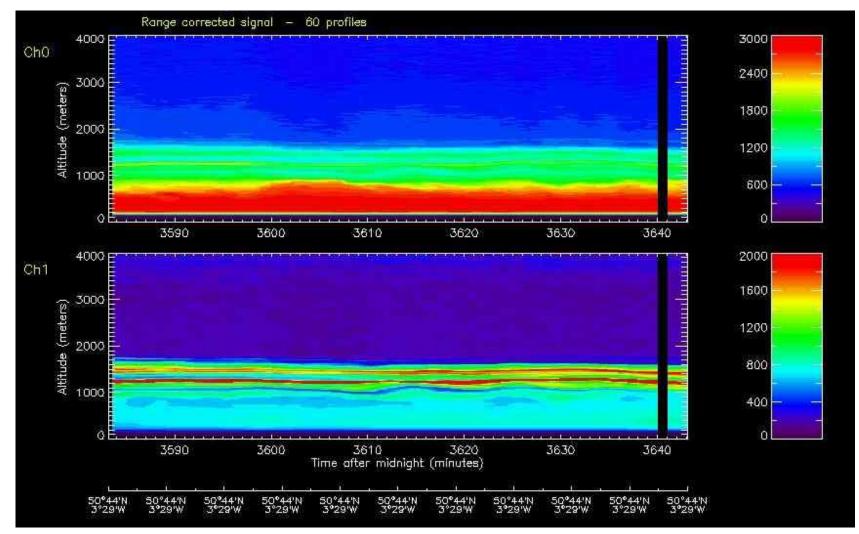

#### Cardington: mixing at ~13.00 UTC?

## The layering/stratification is clearly visible over Exeter (18<sup>th</sup> April).

#### Comparison of particle size estimates

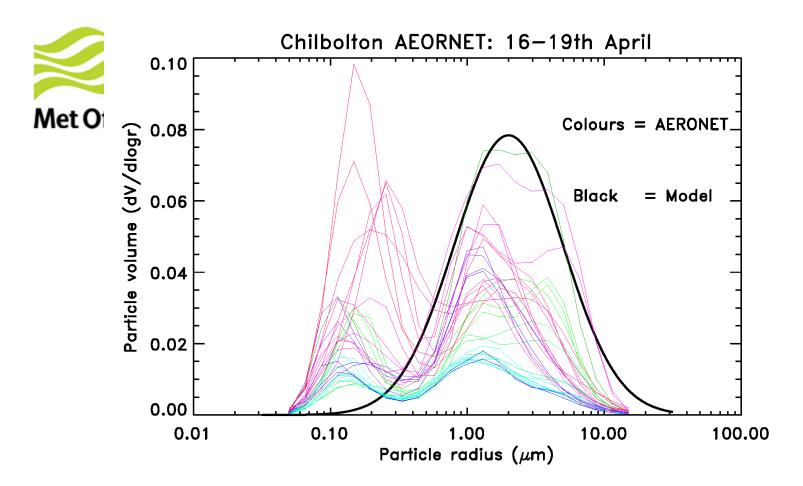

#### Chilbolton: two-colour lidar: r~1 microns Refractive index assumed 1.5-0.001i (Chris Westbrook)

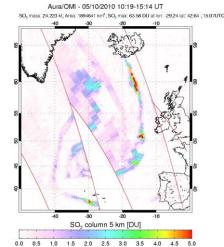

Sun-photometers: r~2 microns (Charles Wrench – Chilbolton/RAL)

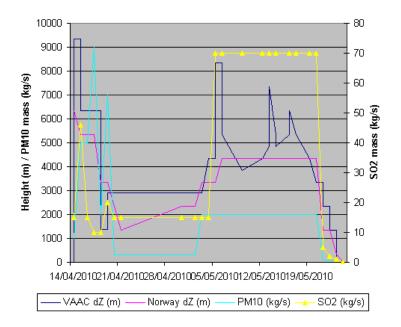

Log-normal distribution with mode radius of  $2\mu m$  and standard deviation of  $2.5\mu m$ 

- Best estimates from satellite measurements of total column SO2
  - Early estimates from study by Norwegian Met Service based on OMI data <u>https://wiki.met.no/emep/ emep\_volcano\_plume</u>
  - We are undertaking a separate study based on IASI data.....

### SO<sub>2</sub> emission scenarios

• Use plume heights as used by VAAC

- Use SO<sub>2</sub> emissions as derived by Norwegian Met Service
- SO<sub>2</sub> emissions based on OMI SO<sub>2</sub> for 15<sup>th</sup> April then scaled according to trends in SO<sub>2</sub> for other days
- To understand the uncertainty in emission strength, we consider 10x and 100x SO<sub>2</sub> strength as well as 'best guess' SO<sub>2</sub> estimates

### NAME AQ Modelling

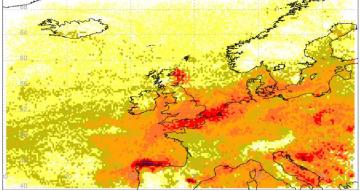

- Lagrangian dispersion model used for routine regional AQ forecasting and modelling
- 3D meteorological fields from the Unified Model
- Complex tropospheric chemistry scheme
- Wet/dry deposition
- For this work we used EMEP (50km) emissions over the whole domain for consistency

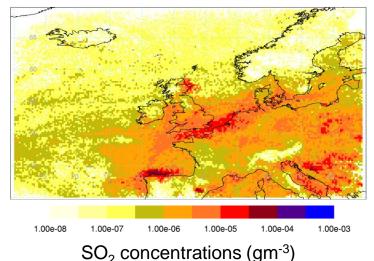

### Model run scenarios

- Compare standard air quality run with / without volcano
- General observation:
  - Using best estimates of source strength magnitude of SO2 reaching boundary layer in UK is v. small, resulting in no increment in AQ index

#### 1300UTC 18/04/2010

#### Without volcano With volcano

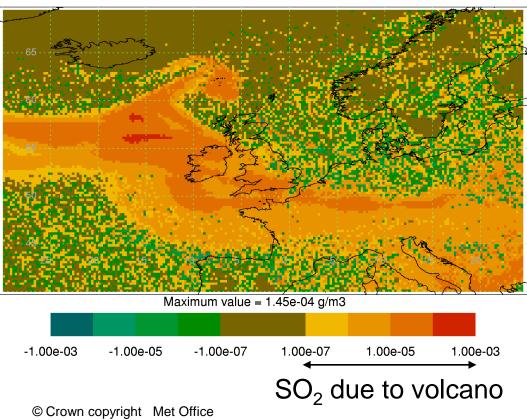

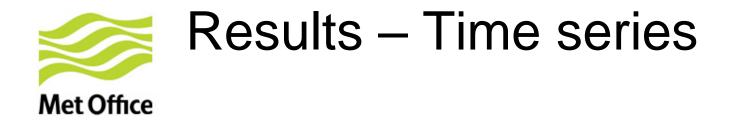

Met Office

 Plot shows difference between 100x strength and 'Control' run with no volcanic emissions

#### 1300UTC 21/04/2010

- SO<sub>2</sub> reaches most of Europe
- Difference reaches 145µgm<sup>-3</sup> at 100x SO<sub>2</sub>
- High plume height means most SO<sub>2</sub> does not reach ground level in 'best estimate' case

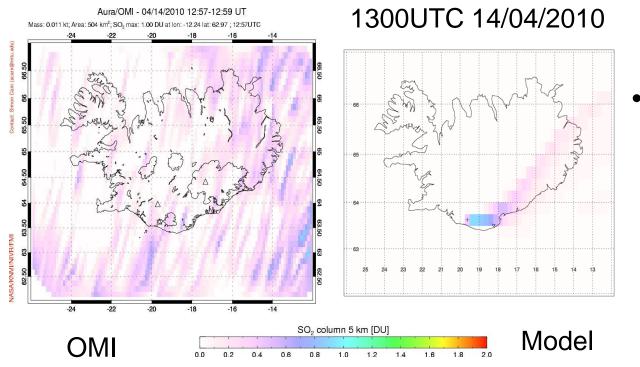

- Shows peaks around 16<sup>th</sup>-19<sup>th</sup> April, 21<sup>st-</sup>23<sup>rd</sup> April and 17<sup>th</sup>-18<sup>th</sup> May are possibly due to Volcanic SO<sub>2</sub>
- Underestimated source strength for some peaks by factor 50?

# Results – Satellite comparisons

 Compare against OMI satellite data by outputting total column SO<sub>2</sub> in Dobson Units

'Best estimate' is generally correct order of magnitude...... ...however

### Satellite comparisons

#### 

- Underestimate of emission strength on 18<sup>th</sup> April
- Corresponds to under prediction on 21<sup>st</sup> April

 Ability to compare modelling scenarios with satellite imagery should allow a better estimate of source strength

- Current best estimates of SO<sub>2</sub> source strength show negligible impact on air quality
- Even at 100x source strength, only a few AURN stations would reach air quality index 2 – comparable to impact of Grangemouth on local sites
- Possible to derive simulated satellite imagery from dispersion modelling to deduce better source strength estimates
