# Executive Summary

The Acid Deposition Monitoring networks were established in 1986 to monitor the composition of precipitation and hence to provide information on deposition of acidifying compounds in the United Kingdom. The Acid Deposition Monitoring Networks comprise two monitoring networks in which rain water samples are collected and analysed. The aim of the first network, known as the "Primary" network, is to provide high quality data which can be used to identify trends with time. The second network, the "Secondary" network, provides information on the spatial distribution of acid deposition in the UK. The measurements made and their interpretation for the period 1986 to 1998 have been presented previously. In addition to the sampling of rainwater at both the Primary and Secondary Network sites, a range of other measurements are made which provide a more complete understanding of precipitation chemistry in the United Kingdom.

Throughout this period consistent operating and analytical procedures have been employed. The deposition data from the networks provide the foundation to the DETR-funded research programme that attempts to determine how acid rain is affecting sensitive ecosystems in the United Kingdom.

This report is the second annual report prepared under the current contract *The Operation and Management of the UK Acid Deposition Monitoring Networks* (EPG 1/3/137) and provides an overview of and the complete sets of measurements made in 1999.

## ***Highlights of the 1999 Measurement***

Apart from sites in Central England and Yorkshire, all the sites had lower rainfall in 1999 than that measured in 1998 by between 1% and 25%. The rainfall was however higher in 1999 than the period mean (1986-1999) at 20 out of the 32 sites by between 2% (Achanarras) to 28% (Thorganby). Lower annual rainfall was however observed on the southern (Barcombe Mills) and western sides (Goonhilly, Yarner Wood, Lough Navar) of the United Kingdom.

Considering a selection of sites in sensitive areas in more detail:

- **Llyn Brianne (Mid Wales):** The rainfall measured at Llyn Brianne was 20% higher in 1999 than the period mean (1986-1999) but comparable to that observed in 1998. The wet deposition of non seasalt sulphate and hydrogen was smaller than that observed in 1998 although the deposition of ammonium and nitrate were higher. Analysis of the long term trends shows a significant decline in the concentration of sulphate and hydrogen. There is however no long-term trend in the concentrations of the nitrogen species although there has been a very slight increase in the deposition in recent years.
- **Bannisdale (Lake District):** The rainfall in 1999 was 17% lower than that measured in 1998 and comparable to the values observed in the drier years of 1995 and 1997. The wet deposition of non seasalt sulphate and hydrogen was lower than that observed in 1998. The trends in the concentrations of sulphate and hydrogen show statistically-significant reductions. The deposition of ammonium and nitrate was slightly lower than that observed in 1998 although the long-term trends in the concentrations showed no real change.

- **Cow Green Reservoir (N Pennines):** The rainfall was 6% lower in 1999 than in 1998 although 15% higher than the period mean. Although closer to the major power station sources of sulphur dioxide, the annual precipitation-weighted mean concentrations of non-seasalt sulphate and hydrogen are slightly smaller than those at Bannisdale and have shown a similar statistically-significant decline over the period 1986 to 1999. The deposition of nitrate and ammonium increased over the measurements made in 1998, although the long-term trends in concentration are not statistically significant.
- **Eskdalemuir (S Scotland):** The rainfall was 13% lower in 1999 than in 1998 although 4% higher than the period mean. The annual precipitation-weighted mean concentrations of non-seasalt sulphate and hydrogen were slightly smaller in 1999 leading to lower depositions of these species. The measurements made in 1999 confirm the previous statistically-significant trends. The deposition of nitrate and ammonium was slightly lower in 1999 than that measured in 1998. The long-term trends in the concentrations of the nitrogen species are not statistically significant.
- **Balquhidder (SW Highlands):** Unlike other sites in the network, the rainfall was 21% higher in 1999 and 9% above the period. The 1999 measurements continue the steady decline in the annual wet deposition of non-seasalt sulphate and hydrogen reported over the period 1986 to 1998. although the concentrations of all species show no statistically-significant trend. The site was moved in 1994 and some caution is needed in interpreting data since then. There is little change in nitrate and ammonium deposition despite the site relocation. 1996 was a very dry year and precipitation-weighted mean concentrations of all ions were unusually large.
- **Pollock, Strathvaich Dam (Northern and Western Highlands):** These sites are relatively unpolluted and, of all the sites in the network, should be most sensitive to the limiting effect of any “background” pollutant levels in precipitation from the Atlantic. The ammonium concentrations in many samples are below the detection limit. Annual mean non-seasalt sulphate concentrations at both sites were below  $10 \text{ } \mu\text{eql}^{-1}$  in 1999. Although no significant trend was observed at Strathvaich Dam in the sulphate concentration over the full measurement period, the more recent measurements at Pollock confirm the downward trend at this site. Deposition of non-seasalt sulphate has declined at both sites, more noticeably at Pollock. Nitrate concentration and deposition show no change at the Strathvaich Dam site. As a result, the non-seasalt sulphate to nitrate ratios in both concentration and deposition have fallen.

The annual mean sulphur dioxide concentration has decreased substantially at all sites with the exception of the Strathvaich Dam site over the period 1986 to 1999. For example, the annual mean concentration at High Muffles has decreased from an annual mean concentration of  $7.3 \text{ } \mu\text{g S m}^{-3}$  in 1987 to  $0.9 \text{ } \mu\text{g S m}^{-3}$  in 1999. Sulphate concentrations in rain do not obviously exhibit the same degree of decrease as that observed for sulphur dioxide. The highest concentrations were observed at Stoke Ferry and Barcombe Mills for the first half of the sampling period - since that time concentrations at both sites decreased by about 25%. The lowest concentrations were consistently measured at Strathvaich Dam.

The annual mean concentrations in 1999 were generally higher than those measured in 1998. This is consistent with the higher concentrations measured for a range of pollutants in 1999. It is likely that the meteorological conditions led to poorer dispersion and dilution of emissions.

## **The Nitric Acid Monitoring Network**

A new monthly nitric acid monitoring network was established at 12 sites during 1999 by the Centre for Ecology and Hydrology (Bush). The network is now operating very smoothly and providing a record with very few missing points. The establishment of the daily site at Barcombe Mills was delayed while planning permission was sought and has only been operational since April 2000. Although most of the initial problems have been overcome, the day-to-day operation of the Chemspec system has been problematic with a large number of sampling problems leading to substantial down time. The improved performance of the Chemspec system will be a priority in the final phase of the project.

Valuable new data have been produced by the network on the behaviour of gaseous and aerosol species involved in transboundary and urban air pollution. In this report, the first measurements from the network are presented. The measurement data have been used to derive the first maps of the spatial distribution of gaseous nitric acid and hydrogen chloride in the UK and of the corresponding aerosol components - nitrate and chloride. Despite the poor performance of the daily system, the results indicate several periods when elevated concentrations of nitric acid were measured.

## **EMEP Intercomparisons**

The measurements made in the UK Acid Deposition Monitoring Networks are reported to international bodies such as UN ECE European Modelling and Evaluation Programme (EMEP) and the World Meteorological Organisation (WMO). As part of a programme of quality control and assurance of the measurement data, AEA Technology participated in the 18<sup>th</sup> laboratory intercomparison exercise organised by EMEP.

Apart from the hydrogen ion concentrations, the measured ion concentrations were in excellent agreement with the expected concentrations for the four samples analysed. The hydrogen ion concentration is measured using a pH probe while the other ions were all measured using the new ion chromatographs. The discrepancy on the hydrogen ion measurements is being checked. It is however clear that the performance of the new ion chromatographs is very good. In the previous intercomparison, the largest differences were noted for magnesium and calcium. In the present intercomparison, the differences are now comparable to those of the other ions.

## **Use of the Measurement Data**

The UK network also forms part of the wider network of the European Monitoring and Evaluation Programme. Results from this network are used to underpin the modelling studies which form the basis of negotiation of UNECE Protocols for controlling the transboundary transport of acidifying pollutants.

The measurements made in the networks have been and continue to be key inputs into the expert reviews of our understanding of acid deposition provided formerly by the Review Group on Acid Rain and more recently by the National Expert Group on Transboundary Air Pollution (NEG-TAP). NEG-TAP was established to advise on transboundary air pollution issues and specifically whether the reductions in the emissions of acidifying pollutants have been effective in promoting the recovery of ecosystems affected by acid deposition.

# 1. Introduction

This is the second annual report prepared on the contract *The Operation and Management of the UK Acid Deposition Monitoring Networks* (EPG 1/3/137), let by the Department of the Environment, Transport and the Regions. The Acid Deposition Monitoring networks were established in 1986 to monitor the composition of precipitation and hence to provide information on deposition of acidifying compounds in the United Kingdom.

The Acid Deposition Monitoring Networks comprise two monitoring networks in which rain water samples are collected and analysed. The aim of the first network, known as the "Primary" network, is to provide high quality data which can be used to identify trends with time. The second network, the "Secondary" network, provides information on the spatial distribution of acid deposition in the UK. The measurements made and their interpretation for the period 1986 to 1998 have been presented in previous reports [e.g. Campbell *et al.*, 1994, 1998; Vincent *et al.*, 1995, 1996, 1998; Hayman *et al.*, 2000].

In addition to the sampling of rainwater at both the Primary and Secondary Network sites, a range of other measurements are made which provide a more complete understanding of precipitation chemistry in the United Kingdom. At the commencement of the contract, the measurement programme comprised the sampling and determination of:

- rainwater composition using a wet-only collector at the "primary" sites on a daily basis;
- rainwater composition using a bulk collector at the Eskdalemuir site on a daily basis;
- rainwater composition using a bulk collector at the "primary" sites on a weekly basis;
- the concentrations of nitrogen dioxide using diffusion tubes on a monthly basis;
- the concentrations of particulate sulphate and sulphur dioxide concentrations at eight sites on a daily basis;
- total inorganic nitrate (TIN) and total inorganic ammonium (TIA) at two sites on a daily basis; and,
- nitric acid and the major constituents of particulate aerosol on a weekly basis at two sites.

The measurement programme was reviewed in February 1999 and significant changes were made to the network. The current monitoring programme comprises:

- the measurement of rainwater composition at the Eskdalemuir site using wet-only collectors on a daily basis and bulk collectors on a daily and weekly basis;
- the measurement of rainwater composition using bulk collectors at 38 other sites on either a weekly or fortnightly basis (following the installation of 7 new fortnightly sampling sites);
- the concentrations of nitrogen dioxide using diffusion tubes on a monthly basis at 32 sites;
- the concentrations of particulate sulphate and sulphur dioxide concentrations at eight sites on a daily basis;
- the measurement of nitric acid and other acidic species in both the gas- and aerosol-phases at 12 sites on a monthly basis (to replace the previous daily TIN/TIA and weekly nitric acid measurements);
- the measurement of nitric acid and other acidic species in both the gas- and aerosol-phases at a single site on a daily basis.

The measurements made in the networks have provided key inputs into the comprehensive reviews of our understanding of acid deposition undertaken by the Review Group on Acid Rain [RGAR, 1990; RGAR, 1997]. In particular, the third and fourth reports of RGAR covered the periods from 1986 to 1988 and from 1992 to 1994, respectively [RGAR, 1990; RGAR, 1997]. The results are currently being used to inform the deliberations of the National Expert Group on Transboundary Air Pollution (NEGTAP) which the Department established in 1999 to advise on transboundary air pollution issues and specifically whether the reductions in the emissions of acidifying pollutants have been effective in promoting the recovery of ecosystems affected by acid deposition.

This report presents a comprehensive summary of the measurements made in the networks for 1999 and includes the first measurements from the new HNO<sub>3</sub> monitoring network and the other new monitoring sites. The report is structured as follows:

- a description of the sampling networks and the sampling techniques employed are presented in Section 2, together with the changes made to the network in 1999;
- an overview of the results from the Acid Deposition Networks for 1999 and concentration maps for non-seasalt sulphate, nitrate, ammonium, hydrogen ion and nitrogen dioxide are presented in Section 3, together with the trends in all acidifying components measured as part of the acid rain monitoring programme;
- a description of the new nitric acid monitoring network and the first measurements are presented in Section 4.

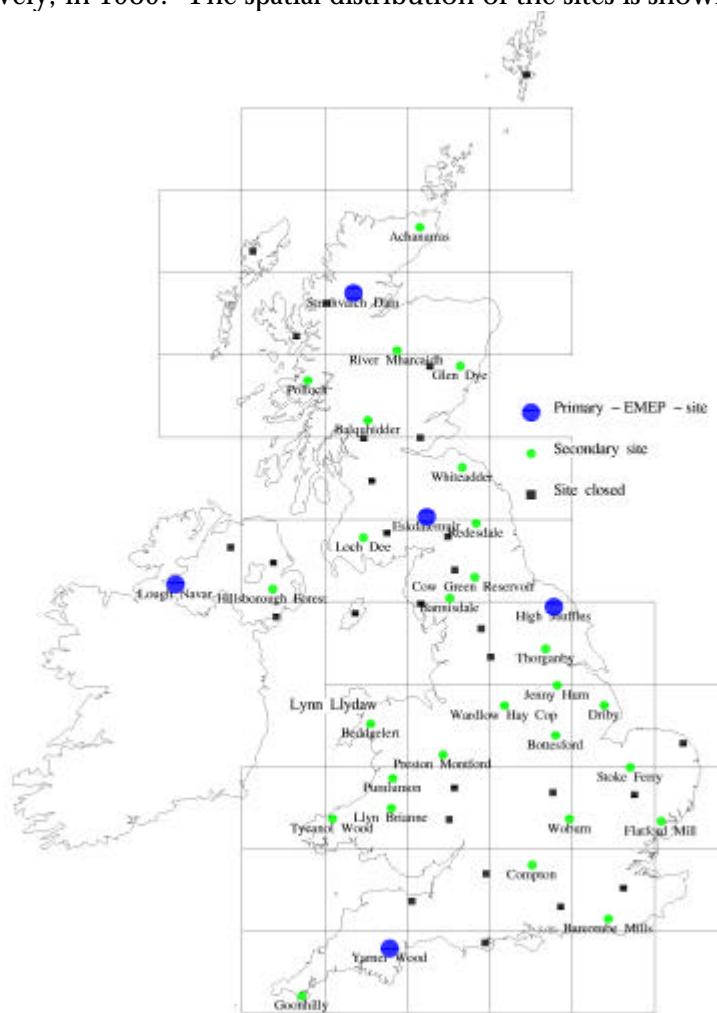

Summary tables of the weekly bulk precipitation composition data for 1999 at the individual sites are presented in Appendix 1. Time series graphs for data collected since 1986 and seasonal variation plots are presented, along with details of the sites themselves. Appendix 2 presents all the annual concentrations at each site since 1986, together with the annual rainfall amounts determined using the bulk rain collector. Appendix 3 describes the geostatistical techniques that have been used to calculate the concentration maps in this report. Concentrations of ions determined for samples collected using the wet-only sampler are presented in Appendix 4.

## 2. The Monitoring Programme

### 2.1 THE ACID DEPOSITION MONITORING NETWORKS

#### 2.1.1 Site Locations

The Acid Deposition Monitoring Networks comprise two monitoring networks in which rainwater samples are collected and analysed. The aim of the first network, known as the “Primary” network, is to provide high quality data which can be used to identify trends with time. The second network, the “Secondary” network, provides information on the spatial nature of acid deposition in the UK. Originally there were 9 primary and 59 secondary sampling sites. Following recommendations from RGAR, both networks were reduced in size to the current 5 and 32 sites, respectively, in 1989. The spatial distribution of the sites is shown in Figure 2.1.

**Figure 2.1: Location of the Current Primary and Secondary Sampling Sites (Also presented are the locations of the sites no longer operating. The 100 km squares show how the sampling site coverage meets the original coverage objective.)**

Seven new sites were established in the early part of 1999 to monitor rainwater composition in ecologically-sensitive locations. The locations of the sites are

- Lochnagar
- Scoat Tarn
- River Etherow
- Llyn Llagi
- Loch Chon/Tinker
- Beaghs Burn
- Crai Reservoir  
(Head of the Valleys)

The sites are shown in Figure 2.2.

The rainwater samples are collected on a fortnightly basis using bulk collectors.

**Figure 2.2: The New Bulk Rainwater Sites.**

In addition to the sampling of rainwater composition, a range of other parameters are measured to provide a more complete understanding of precipitation chemistry in the United Kingdom. The measurement programme was reviewed in February 1999 by leading members of the UK Acid Rain community and significant changes were proposed and implemented. The current monitoring programme comprises the sampling and determination of:

- rainwater composition using bulk and wet-only collectors at the Eskdalemuir site on a daily basis;
- rainwater composition using bulk collectors at the other 38 network sites on either a weekly or fortnightly basis;
- the concentrations of nitrogen dioxide using diffusion tubes on a monthly basis at 32 sites;
- the concentrations of particulate sulphate and sulphur dioxide concentrations at eight sites on a daily basis;
- the concentrations of nitric acid and other acidic species in both the gas- and aerosol-phases at 12 sites on a monthly basis (see Section);
- the concentrations of nitric acid and other acidic species in both the gas- and aerosol-phases at a single site on a daily basis.

While the new nitric acid monitoring network was being established, the following measurements were continued to allow a period of overlap with those made in the new nitric acid monitoring network:

- total inorganic nitrate and total inorganic ammonium at two sites on a daily basis and
- nitric acid and the major constituents of particulate aerosol on a weekly basis at two sites.

The sampling techniques used to make these measurements are summarised in Sections 2.2.

### **2.1.2 Site Operations**

The sites in operation in 1999 are listed together with the local operators who perform the weekly change over of samples in Table 2.1, Table 2.2 and Table 2.3.

## **2.2 SAMPLING TECHNIQUES**

### **2.2.1 Precipitation**

Weekly or Fortnightly precipitation samples were collected in bulk collectors at 39 sites using a collector designed by Hall [1986]. An assessment of the collection efficiency of the bulk collector is provided by Stone and Tily [1992]. For the two year period 1986 to 1987, the bulk collector was found to have collection efficiencies which ranged from 77% to 99% when compared to the 5 inch meteorological rain gauge.

Acid deposition occurs primarily by wet and dry deposition. The wet-only collector, developed at the Warren Spring Laboratory (which now forms part of AEA Technology), is a daily precipitation collector. The collector incorporates a number of features designed to measure the wet deposition component, minimise the effect of dry deposition, preserve sample integrity, record associated tipping bucket volume data and allow unattended operation for up to eight days.

### **2.2.2 Sulphur Dioxide and Particulate Sulphate**

The concentrations of particulate sulphate and sulphur dioxide were determined by first collecting a sample using eight-port bubbler instruments (AGL, Hitchin). Particulate sulphate was collected by drawing air through a Whatman 40 filter. Sulphur dioxide is collected by passing the air through a hydrogen peroxide solution where sulphur dioxide is oxidised to sulphate. The sulphate concentrations are determined by ion chromatography.

In addition to the daily sampling reported here, further monitoring of sulphur dioxide - *The Rural SO<sub>2</sub> Monitoring Network* - is undertaken as part of the Acid Deposition Processes contract let to the Centre for Ecology and Hydrology, Bush.

### **2.2.3 Nitrogen Dioxide**

Diffusion tubes have been used to measure nitrogen dioxide concentrations at the Primary and Secondary Network sites. Tubes were mounted on the upright of the rain collector stand and are exposed for twelve four or five week periods throughout each year.

### **2.2.4 Total Inorganic Nitrate and Total Inorganic Ammonium**

Total inorganic nitrate (TIN) and total inorganic ammonium (TIA) were collected on a daily basis using single-stage filter packs impregnated with sodium hydroxide and citric acid to absorb TIN and TIA, respectively. The filter packs are held within a protective hood and exposed throughout the sampling period. This is a recommended EMEP method.

▲ The Beddgelert site was closed down July 1996 and replaced by Llyn Llydaw, O.S. co-ordinates SH 638549. The site is situated within the Environmental Change Networks' compound in the Snowdon Horseshoe

Following the strategic review of the networks in 1999, this sampling programme will be replaced. The existing measurement programme was discontinued at High Muffles on the 7<sup>th</sup> April 1999 and will continue at Eskdalemuir until 30<sup>th</sup> September 2000 to allow a period of overlap with the replacement measurement programme (see Section 4).

### **2.2.5 Nitric Acid**

A two-stage filter-pack is used in the monitoring network for nitric acid. Air is drawn through the filter pack at 5 l min<sup>-1</sup>. Particles are trapped on the PTFE membrane while the nylon filter absorbs nitric acid (and other gases of interest such as HCl). The filters are exposed for weekly periods. The samples collected are extracted using an alkaline extractant and analysed by ion chromatography. The samples collected under dry summer conditions are likely to under-read as ammonium nitrate may volatilise during sampling. During cool wet winter conditions nitric acid may be absorbed by the front filter. The measurement technique does not give quantitative measurements and is used for indicative purposes only.

As part of the strategic review of the networks (Section 2.1), this sampling programme has been replaced by the new nitric acid monitoring programme (Section 4). The existing measurement programme was discontinued at the High Muffles and Stoke Ferry sites from December 2000.

## **2.3 ANALYTICAL PROCEDURES**

### **2.3.1 Sample Registration and Preparation**

As for previous years, approximately 10,000 samples were received and analysed by the laboratory. Samples returned to AEA Technology were logged on a computerised sample register and their volumes recorded. Sample preparation and handling were carried out using standard operating procedures.

On receipt in the analytical laboratory rainwater samples were sub-sampled into polyethylene bottles (Nalgene). The pH and conductivity were recorded and the samples filtered through 1µm disposable filters to remove insoluble particulate material and micro-organisms that might compromise sample integrity before analysis. The samples were then stored at 4°C until analysis by ion chromatography. Samples were analysed for: sulphate, nitrate, chloride, phosphate, sodium, magnesium, calcium, potassium, pH and conductivity. Analysis was usually completed within one month.

### **2.3.2 Analysis**

Samples were analysed using NAMAS accredited methods. All samples with exception of diffusion tubes are analysed using ion chromatography.

The rapid analysis of a large number of rain water samples in which concentrations vary over several orders of magnitude is a complex task. To verify the analytical results, the ion balance, I (Equation 1), is calculated for each rainwater sample.

$$I = \frac{2(\Sigma c - \Sigma a)}{\Sigma c + \Sigma a} \quad (\text{Equation 1})$$

where  $S_c$  = sum of cation concentrations in equivalents ( $\mu\text{eq l}^{-1}$ ) and  $S_a$  = sum of anion concentrations in equivalents ( $\mu\text{eq l}^{-1}$ ). A correction is estimated for the concentration of bicarbonate in samples which have a pH greater than 5.5. Samples which fall outside the criteria listed in Table 2.4 are submitted for reanalysis. The reanalysis is usually completed within four months of sampling.

**Table 2.4 - Ion Balance Criteria Used to Select Samples for Reanalysis**

Ionic strength concentration range ( $\mu\text{eq l}^{-1}$ )	Samples are resubmitted when the ion difference (%) is:
Less than 50	> 60
50-100	> 30
Greater than 100	> 15

Typically, 10-15% of the samples would fail the criteria and would be reanalysis. This failure rate would be reduced on reanalysis. In recent years, the number of samples failing the criteria has increased significantly because of the high calcium and magnesium ion concentrations measured using the existing ion chromatographs (see Section 2.3.3).

### 2.3.3 Introduction of New Ion Chromatographs

Two new ion chromatographs have been purchased by Harwell Scientifics. One ion chromatograph will be dedicated to the measurement of cations, the other to the determination of anions. Following extensive tests of the performance of the two new ion chromatographs, Harwell Scientifics Limited have gained formal accreditation for the new ion chromatographs from the United Kingdom Accreditation Service.

The tests undertaken have clearly indicated that the new instruments give very reproducible results and are in excellent agreement with the measurements made using the old chromatographs. The performance of the new instruments is better with regard to the measurement of the base cations, calcium and magnesium. The concentrations are generally lower than those measured on the old instruments. Extensive tests have been undertaken to understand this discrepancy but the origin has not been identified. Operationally, the high calcium and magnesium ion concentrations have resulted in a significant number of reanalyses. It is expected that the number of reanalyses required will be reduced as a result.

At a meeting held between AEAT and HSL to review the performance of the new instruments in the summer of 2000, the following changeover was implemented:

- Rainwater Samples: *All samples collected during 2000 would be analysed with the new ion chromatographs. The samples collected during 2000 which have been analysed so far using the old ion chromatograph will be reanalysed.*
- Daily Bubbler Samples: *These are only analysed for sulphate. The intention was to continue to use the old ion chromatograph for these measurements.*
- Weekly Bubbler Samples: *This is the measurement programme undertaken in the Rural SO<sub>2</sub> Monitoring network, which AEA Technology operates under subcontract to CEH Edinburgh as part of the Acid Deposition Processes project. The samples are only analysed for sulphate. The intention is*

*to continue to use the old ion chromatograph for these measurements until the end of the contract which expired at the end of October.*

The tests undertaken by Harwell Scientifics Limited indicate that the performance of the two instruments are identical within their respective measurement errors. This is important as the data collected in the networks are used to identify trends over time. Any step changes introduced will make the identification of such trends more difficult.

#### 2.3.4 Changes to the Sample Registration System

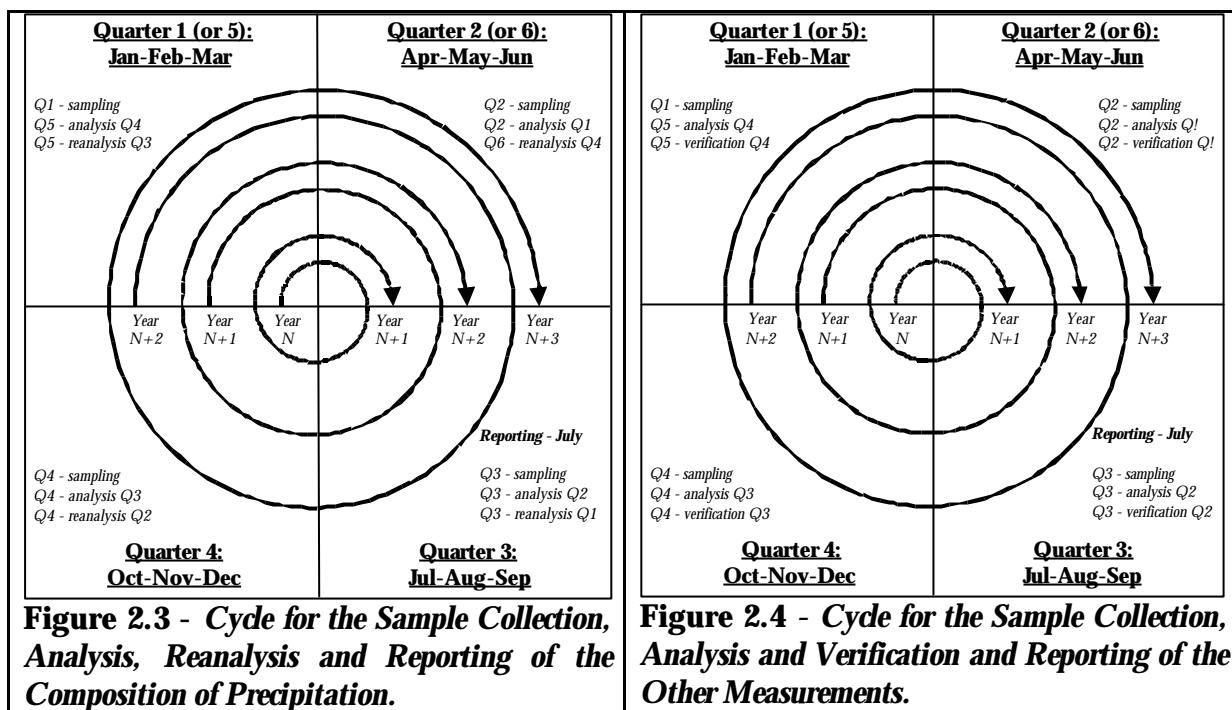

A new sample registration system has been developed to replace the existing system which is used to process the large number of samples collected in the networks. The new system has been developed using Microsoft ACCESS and is now fully operational. The system contains the following additional functionality:

- *Data Reconciliation:* For many of the samples collected, air is drawn through a filter paper (*e.g.*, the collection of aerosol material to give the particulate sulphate concentration) or a solution (*e.g.*, the hydrogen peroxide bubbler for SO<sub>2</sub>). The analysis of the samples give the amount or concentration of material present in the solution or extract. The total volume of air drawn through the sampler is needed to convert the analytical results into air concentrations. Previously, the total volume was derived from the information placed in the sample registration system when the individual samples were registered. This had to be extracted from the sample registration system and combined with the analytical results. The process was inefficient as the sample volume and analytical results needed to be reconciled and the datasets were held on different computer platforms with different operating systems. A facility has been included to perform this calculation within the new registration system.
- *Data Verification:* A facility has also been added to calculate the ion balance of the rainwater samples automatically and hence to identify the samples which need to be reanalysed. In the previous sample registration system, this calculation was made outside the registration system. The incorporation of these calculations in the registration system has significantly streamlined the data verification process. It is intended that the sample registration system will produce a ratified dataset which can be placed on the National Air Quality Information Archive or into the existing Air Pollution database for further data analysis.

The presence of these functions in the new sample registration system has improved the efficiency of the sample registration and subsequent data processing and verification.

### 2.4 DATA REPORTING CYCLE

Sample collection, analysis, reanalysis and verification is a continuous process. Figure 2.3 and Figure 2.4 define the reporting cycles for the measurements made in the monitoring programme. Reanalysis is only undertaken for the composition of precipitation using the ion balance as the criterion. Simple data verification is undertaken for the other measurements. The cycles show that the measurements made in Year N would be available by July of Year N+1. Although the existing cycles approach this, it is intended to adhere to these reporting cycles more closely.

# 3. 1999 Measurements and Trends

## 3.1 DATA SUMMARY

The complete set of precipitation measurements made in the Acid Deposition Monitoring Networks during 1999 is provided in Appendix 1. For each site, information is provided about the site and the measurements made. Plots are included in Appendix 1 which show (a) the trend in the annual precipitation-weighted mean concentrations for non-seasalt sulphate, nitrate, ammonium and hydrogen ion since 1986 and (b) the trend in the annual rainfall and in the corresponding annual deposition of the four species since 1986. It should be noted that the tables in Appendix 1 contain all the analytical results obtained, including those samples affected by contamination by birdstrike. A phosphate concentration  $> 0.1 \text{ mg P l}^{-1}$  (or  $> 9.7 \mu\text{eq l}^{-1}$ ) was taken as evidence of contamination. Although all these samples have been included in the tables, they were not included in the calculation of annual means. The mean annual rainfall and the precipitation-weighted mean annual concentrations of all ions for the period from 1986 to 1999 are also tabulated in Appendix 2. The rainfall totals presented in Appendix 2, Table 10 include all samples collected and are therefore sometimes higher than the totals presented in this section.

The trends shown in the two plots varies from site to site (Appendix 1), although in general annual precipitation-weighted mean non-seasalt sulphate and hydrogen ion concentrations have tended to decline whereas nitrate and ammonium have not changed much at all. A box has been included in Appendix 1 which contains a statistical summary of the trends of the four ions shown in the plots.

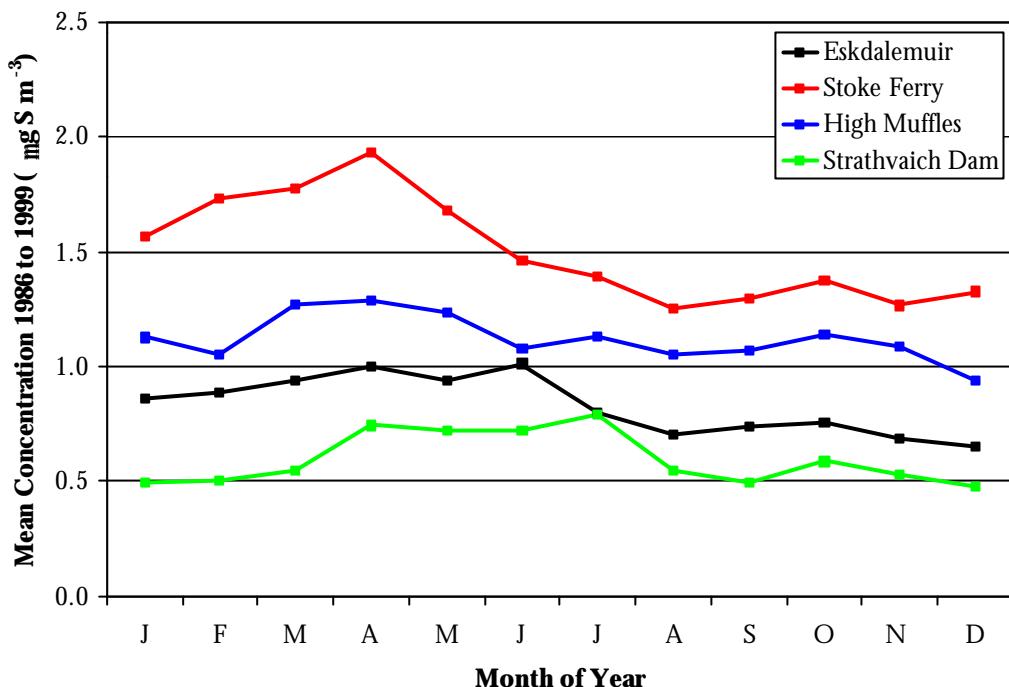

Previously, appendix 1 also included a figure for each site which showed the seasonal variation in the concentrations. The seasonal plots presented previously [see Hayman *et al.*, 2000] clearly showed that the largest concentrations of both non-seasalt sulphate and nitrate occur in the period from April to June at most of the sites. This is partly a consequence of the seasonal variation of emissions and of the oxidising capacity of the atmosphere, as demonstrated by the seasonal variation observed in particulate sulphate (see Figure 3.1). However, the variation in concentration of particulate sulphate concentration is much smaller than that of non-seasalt sulphate in precipitation. The concentrations of ions in precipitation are also affected by the seasonal variation in rainfall amount. The monthly mean rainfall amount tends to be smaller in early summer than in the rest of the year and the inverse correlation between rainfall amount and the concentrations of non-seasalt sulphate, nitrate, ammonium results in a corresponding opposite seasonal variation.

## 3.2 PRECIPITATION CHEMISTRY

### 3.2.1 Highlights of the 1999 Measurements

Apart from sites in Central England and Yorkshire, all the sites had lower rainfall in 1999 than that measured in 1998 by between 1% and 25%. The rainfall was however higher in 1999 than the period mean (1986-1999) at 20 out of the 32 sites by between 2% (Achanarras) to 28% (Thorganby). Lower annual rainfall was however observed on the southern (Barcombe Mills)

and western sides (Goonhilly, Yarner Wood, Lough Navar) of the United Kingdom. The rainfall was also lower than the 30-year average for the period 1941-1970 at 29 of the sites by between 2% (Jenny Hurn) and 44% (Whiteadder). Only the sites at Pumplumon, Thorganby, High Muffles and Loch Dee showed an increase.

**Figure 3.1 Seasonal Variation in the Particulate Sulphate Concentration at 4 Primary Sites as averages for the years 1986-1999.**

Considering a selection of sites in sensitive areas in more detail:

- **Llyn Brianne (Mid Wales):** The rainfall measured at Llyn Brianne was 20% higher in 1999 than the period mean (1986-1999) but comparable to that observed in 1998. The precipitation-weighted concentrations and hence wet deposition of non seasalt sulphate and hydrogen were lower than those observed in 1998 although the concentration and deposition of ammonium and nitrate were higher. Analysis of the long term trends shows a significant decline in the concentration of sulphate and hydrogen. There is however no long-term trend in the concentrations of the nitrogen species although there has been a very slight increase in the deposition in recent years.
- **Bannisdale (Lake District):** The rainfall in 1999 was 17% lower than that measured in 1998 and comparable to the values observed in the drier years of 1995 and 1997. The trends in the concentrations of sulphate and hydrogen show statistically-significant reductions. The deposition of ammonium and nitrate was slightly lower than that observed in 1998 although the long-term trends in the concentrations showed no real change.
- **Cow Green Reservoir (N Pennines):** The rainfall was 6% lower in 1999 than in 1998 although 15% higher than the period mean. Although closer to the major power station sources of sulphur dioxide, the annual precipitation-weighted mean concentrations of non-

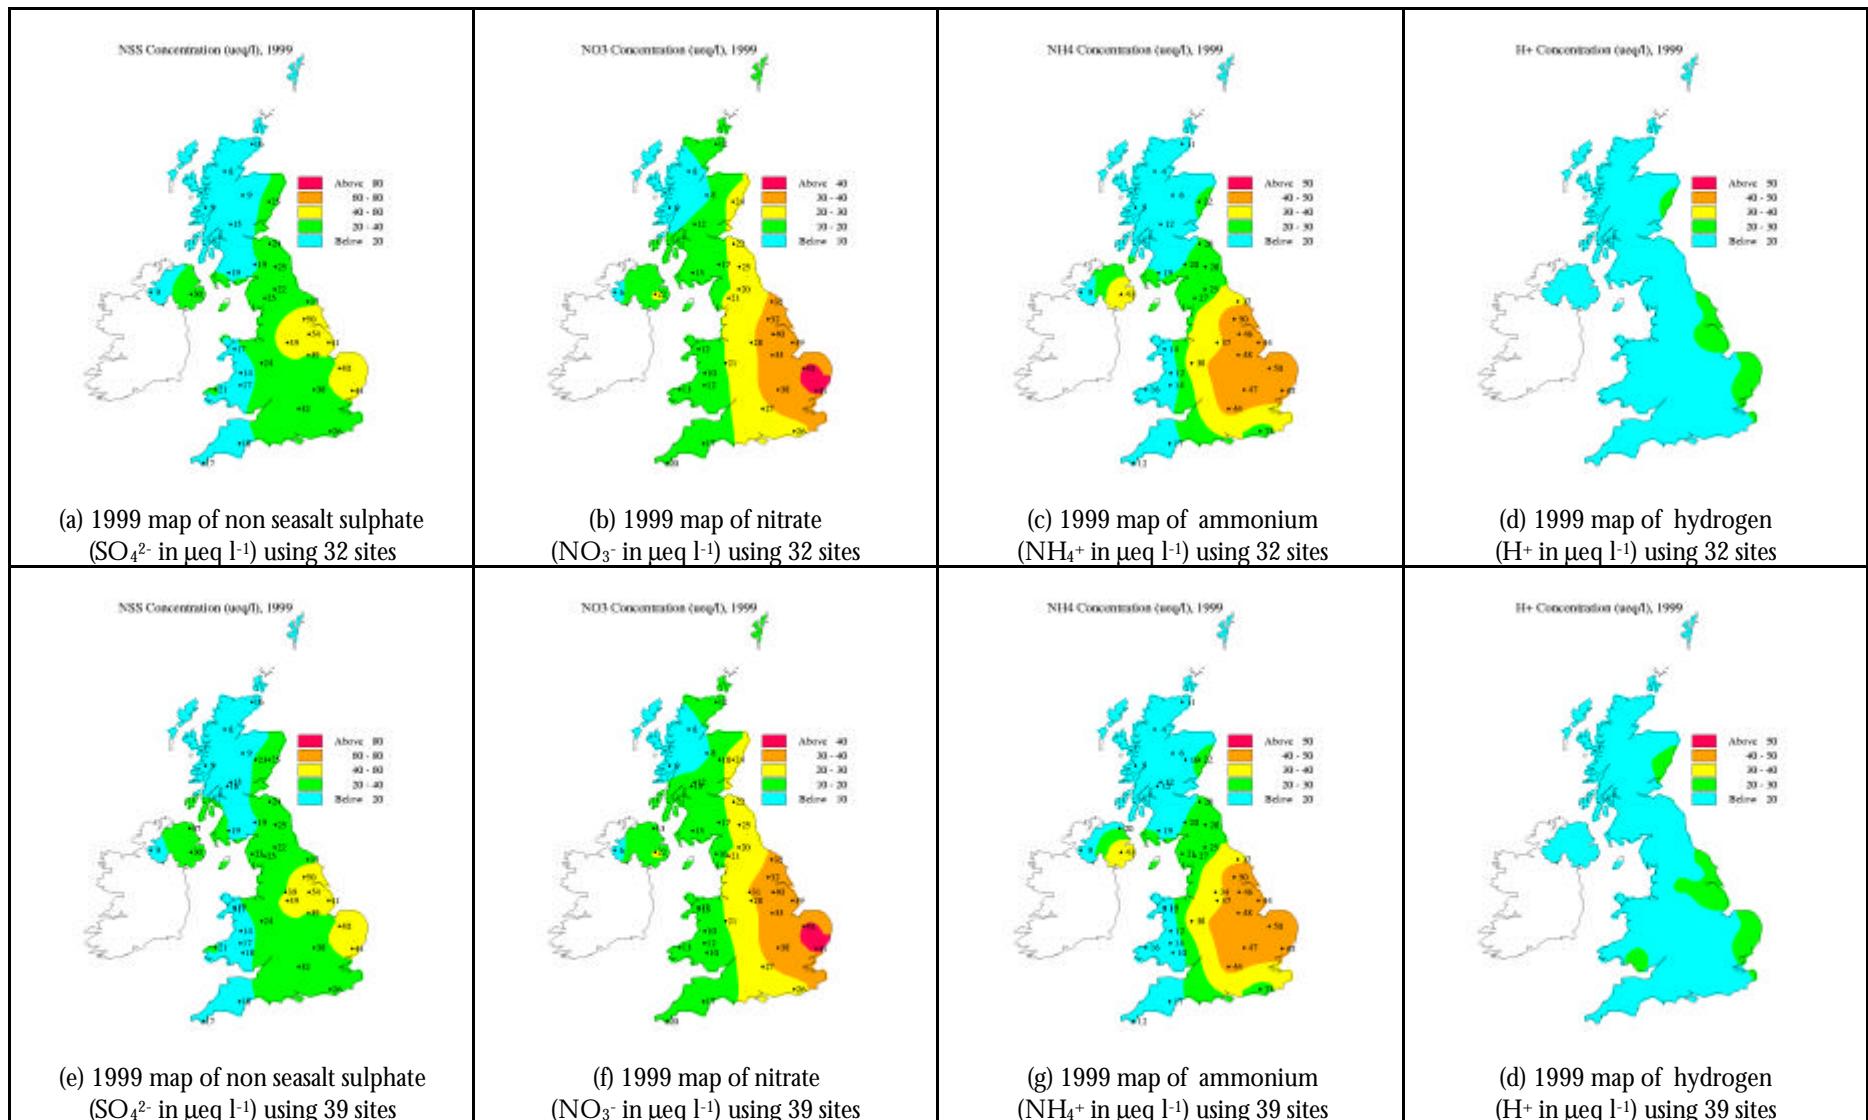

seasalt sulphate and hydrogen are slightly smaller than those at Bannisdale and have shown a similar statistically-significant decline over the period 1986 to 1999. The deposition of nitrate and ammonium increased over the measurements made in 1998, although the long-term trends in concentration are not statistically significant.

- ***Eskdalemuir (S Scotland)***: The rainfall was 13% lower in 1999 than in 1998 although 4% higher than the period mean. The annual precipitation-weighted mean concentrations of non-seasalt sulphate and hydrogen were slightly smaller in 1999 leading to lower depositions of these species. The measurements made in 1999 confirm the previous statistically-significant trends. The deposition of nitrate and ammonium was slightly lower in 1999 than that measured in 1998. The long-term trends in the concentrations of the nitrogen species are not statistically significant.
- ***Balquhidder (SW Highlands)***: Unlike other sites in the network, the rainfall was 21% higher in 1999 and 9% above the period. The 1999 measurements continue the steady decline in the annual wet deposition of non-seasalt sulphate and hydrogen reported over the period 1986 to 1998. although the concentrations of all species show no statistically-significant trend. The site was moved in 1994 and some caution is needed in interpreting data since then. There is little change in nitrate and ammonium deposition despite the site relocation. 1996 was a very dry year and precipitation-weighted mean concentrations of all ions were unusually large.
- ***Pollock, Strathvaich Dam (Northern and Western Highlands)***: These sites are relatively unpolluted and, of all the sites in the network, should be most sensitive to the limiting effect of any “background” pollutant levels in precipitation from the Atlantic. The ammonium concentrations in many samples are below the detection limit. Annual mean non-seasalt sulphate concentrations at both sites were below  $10 \mu\text{eql}^{-1}$  in 1999. Although no significant trend was observed at Strathvaich Dam in the sulphate concentration over the full measurement period, the more recent measurements at Pollock confirm the downward trend at this site. Deposition of non-seasalt sulphate has declined at both sites, more noticeably at Pollock. Nitrate concentration and deposition show no change at the Strathvaich Dam site. As a result, the non-seasalt sulphate to nitrate ratios in both concentration and deposition have fallen.

### 3.2.2 Concentration Maps for 1999

The spatial concentration patterns for hydrogen ion, non-sea sulphate, nitrate and ammonium are presented in Figure 3.2a to d for the original 32 bulk rainwater sites in the networks. Figure 3.2e to h present the maps that include the measurements from the original 32 bulk rainwater sites in the network and the 7 new sites established in 1999. The parameters used in the interpolation are presented in Appendix 3.

In previous years, in addition to concentration maps, deposition maps have been determined using rainfall fields supplied by the Meteorological Office. As these data are not available, only concentration maps are presented.

**Figure 3.2: Precipitation-weighted concentration maps of non seasalt sulphate, nitrate, ammonium and hydrogen for 1999.**

### 3.2.3 Precipitation Chemistry Trends

Figure 3.3 and Figure 3.4 show the monthly total and running annual average<sup>1</sup> of the monthly total deposition for non-seasalt sulphate and nitrate at each of the primary sites in the network. The data shown in these figures were derived from the samples collected by the weekly bulk collectors. The plots show that there is (a) a large month-to-month variation in deposition at all sites, (b) a variation in the average deposition between sites and (c) a variation in the long-term trends in deposition over the period 1986 to 1999.

The spatial variation in the long-term trend in wet deposition is, perhaps, surprisingly small between these sites. For the sites at Yarner Wood, Barcombe Mills, Stoke Ferry, Eskdalemuir and Glen Dye, the average monthly deposition of sulphate was close to 0.04 to 0.05 g S m<sup>-2</sup> month<sup>-1</sup> and nitrate around 0.03 g N m<sup>-2</sup> month<sup>-1</sup>. There was greater wet deposition of sulphate at the High Muffles site (0.05 to 0.07 g S m<sup>-2</sup> month<sup>-1</sup>) than at the other sites. The wet deposition of nitrate was however similar to that at the other sites. The Strathvaich Dam and Lough Navar sites received less deposition of both pollutants, around 0.02 to 0.03 g S m<sup>-2</sup> month<sup>-1</sup> and around 0.01 to 0.02 g N m<sup>-2</sup> month<sup>-1</sup>.

The concentrations of non-sea salt sulphate and nitrate in rainwater (and also of sulphur dioxide, and particulate sulphate) are clearly decreasing in some regions of the United Kingdom while in other regions the change in concentration is less easy to discern. At all sites, the wet deposition of sulphate has tended to decrease, albeit with varying significance. The greatest decreases were observed at Stoke Ferry and Barcombe Mills, both of which are close to major UK sources. The trend in nitrate deposition is more variable; there is no significant change.

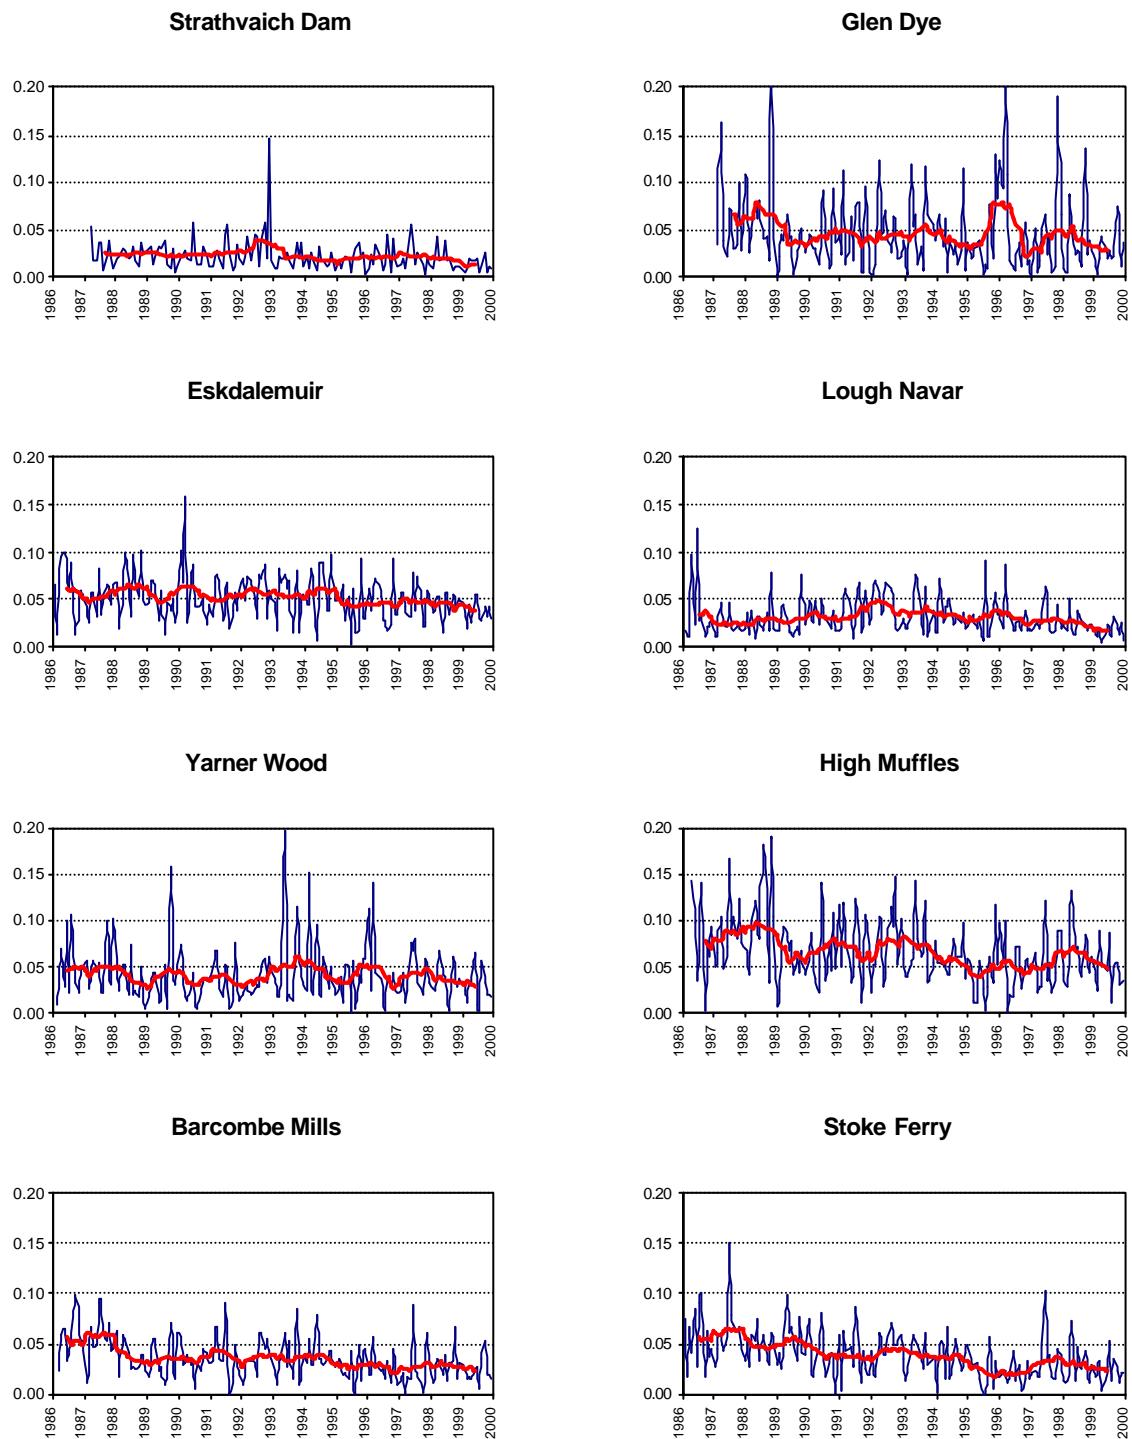

Maximum monthly deposition totals of both nitrate and non-seasalt sulphate were as large at Yarner Wood and Glen Dye as at High Muffles, even though the latter is close to the largest UK point sources of sulphur dioxide. This illustrates the importance of episodic meteorological conditions at these sites. The impact of the March 1996 episode of long-range transported sulphate and nitrate can be clearly seen in the monthly curves for Glen Dye.

Analysis of the data has been undertaken to quantify the significance of the trends. The concentration data have been analysed using a linear least squares approach. The regression coefficient, or slope of the trend line, will have units of  $\mu\text{eq l}^{-1} \text{ year}^{-1}$ . Associated with the regression analysis is a value called the F statistic. The F statistic is a measure of how successfully the linear regression can account for the variation in the dataset. It is formally defined as the ratio of the variance due to regression, standardised by the respective degrees of freedom ( $MS_R$ ), to the variance about the regression also standardised by the respective degrees of freedom ( $MS_E$ ). The value of the F statistic can be compared to points on an appropriate F distribution curve. If the value is greater than a certain (critical F) value, it is assumed that a real, statistically significant, change in the concentration has occurred.

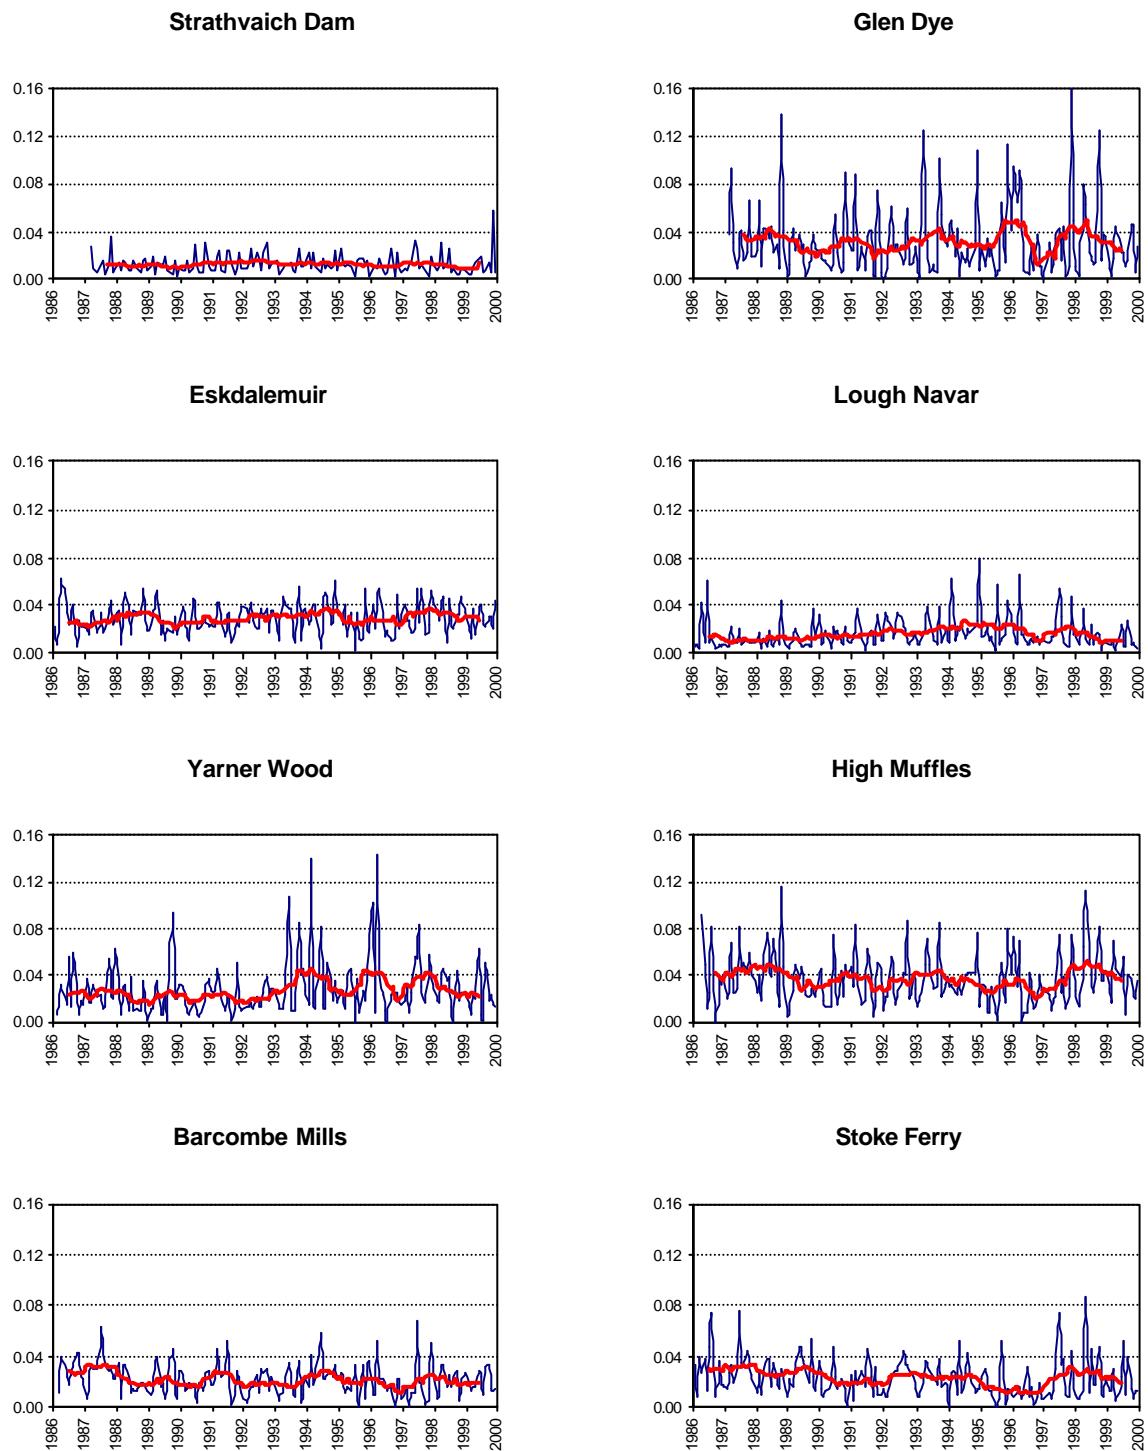

In the analysis presented below, a 5% significance level has been used. This means that there is a 5% chance that the trend is not significant. Further, the “strength” of the observed trend is quantified using multiples of the ratio of the calculated F statistic to the critical F value. These multiples (more or less arbitrarily defined) are presented in Table 3.1.

---

<sup>1</sup> In this report, the running annual mean is an average over 365 days and is centred on the midpoint of the interval. It removes the seasonal variation, thereby allowing the underlying trend to be discerned more clearly.

**Figure 3.3: Monthly mean and running annual mean of wet deposited non-seasalt sulphate ( $\text{g S m}^{-2} \text{ month}^{-1}$ )**

**Figure 3.4: Monthly mean and running annual mean of wet deposited nitrate ( $\text{g N m}^{-2} \text{month}^{-1}$ )**

**Table 3.1: Strength of the Significance of the Trend.**

Ratio	Value of ratio	Symbol	Comment
F calculated/F critical	ratio < 1	-	No Significant trend
F calculated/F critical	1 < ratio < 2	+	Significant trend detected
F calculated/F critical	2 < ratio < 5	++	Moderate trend detected
F calculated/F critical	5 < ratio < 10	+++	Strong trend detected
F calculated/F critical	10 < ratio < 20	++++	Very strong trend detected

Table 3.2 presents a summary of the trend analysis performed on the non-sea salt sulphate concentrations measured at the sampling sites in the acid rain monitoring network. Sites that show a very strong trend are situated in relatively dry locations, often downwind of major sources. Values of “F<sub>calculated</sub>/F<sub>critical</sub>” less than one indicate that no statistically significant trend can be detected. This most often occurs for sites which are in the more remote parts of the United Kingdom.

**Table 3.2: Summary of the Trend Analysis for nss-Sulphate Observed at the Acid Deposition Monitoring Network Sites and its Significance.**

Sampling site	Site code	$\mu\text{eql year}^{-1}$	% change $\text{year}^{-1}$	Trend status

Yarner Wood	5008	-0.47	-1.62	-

Although the primary focus of the monitoring programme has been on the deposition of nitrate and non seasalt sulphate, there is increasing interest in the other components of rainwater, such as the base cations (Na, K, Mg and Ca).

### 3.3 SULPHUR DIOXIDE AND PARTICULATE SULPHATE

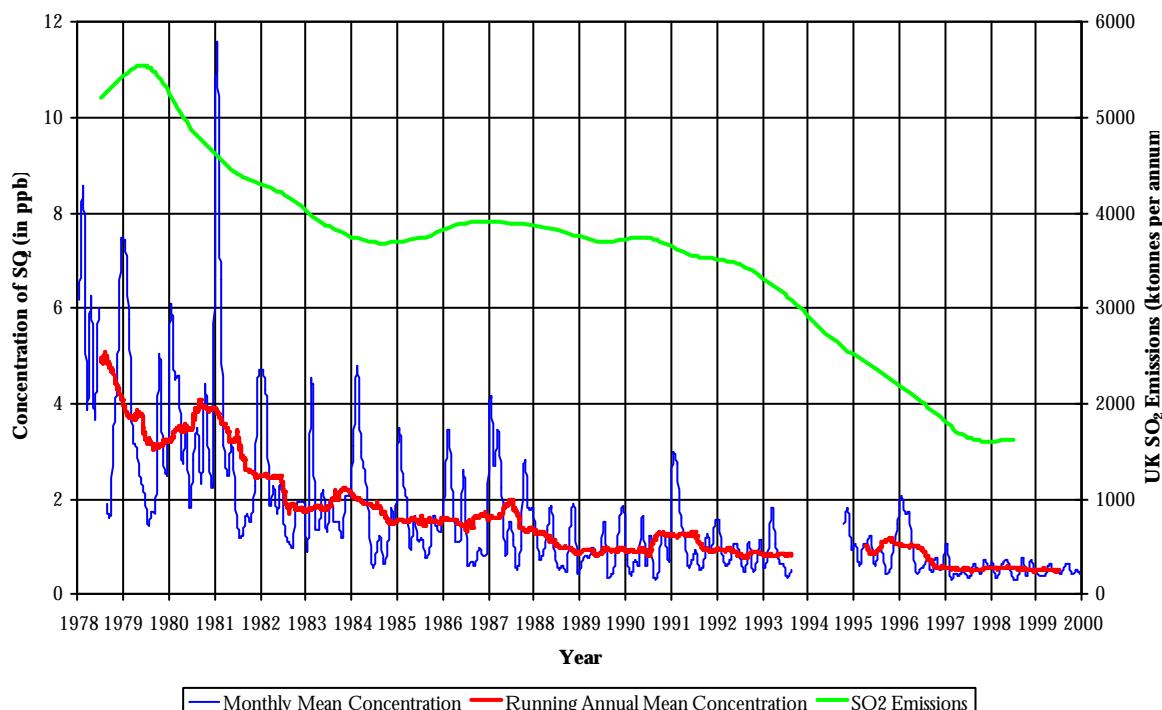

#### 3.3.1 The 1999 Measurements

A summary of the measurements of sulphur dioxide and of particulate sulphate made at the eight primary sites is presented in Appendices 4.1 and 4.2 respectively.

The measurement of sulphur dioxide concentrations is also made in the Rural SO<sub>2</sub> Monitoring Network which is covered by a separate DETR contract (under sub-contract from the NERC). The mapping of the sulphur dioxide concentration is undertaken under that contract and is not discussed in this report. Data reports have been prepared by Vincent and Campbell [1996], Hasler and Downing [1999] and Hasler *et al.* [2001a, 2001b].

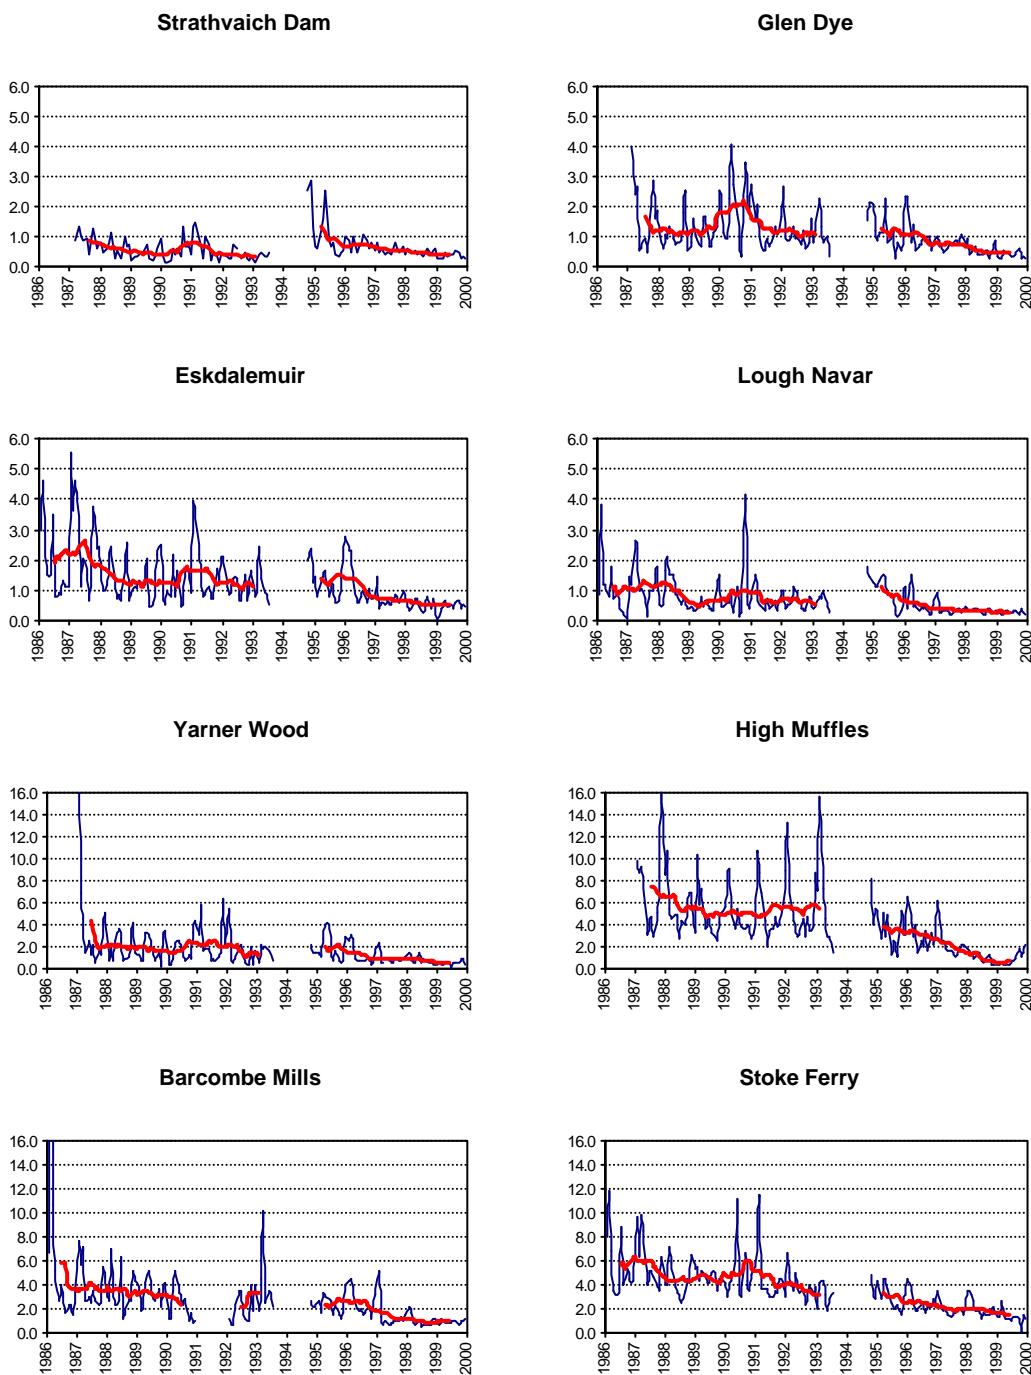

#### 3.3.2 Trends in Sulphur Dioxide

Figure 3.5 shows both the monthly mean concentrations and running annual mean concentrations of sulphur dioxide at Eskdalemuir. As reported previously, the largest change in the concentration occurred between 1980 and 1990, during which time the average concentration decreased by a factor of three from around 4.5 ppb to 1.5 ppb. From 1990 to 1999, the concentration has decreased by a similar factor of two to three, to less than 0.5 ppb. The figure also shows the large month-to-month variation and clearly illustrates how concentrations are increased during cold winter months with relatively high emissions and poor vertical dispersion of pollutants.

**Figure 3.5: Trends in the concentration of sulphur dioxide observed at Eskdalemuir since 1978**

The monthly and running annual mean concentrations of sulphur dioxide measured at each of the primary sites are presented in Figure 3.6. The strong seasonal variation is particularly noticeable at the High Muffles site, close to major sulphur dioxide sources. The annual mean sulphur dioxide concentration has decreased substantially at all sites with the exception of Strathvaich Dam over the period 1986 to 1999. For example, the annual mean at High Muffles has decreased from an annual mean concentration of  $7.3 \mu\text{g S m}^{-3}$  in 1987 to  $1.7 \mu\text{g S m}^{-3}$  in 1997 and  $0.9 \mu\text{g S m}^{-3}$  in 1999.

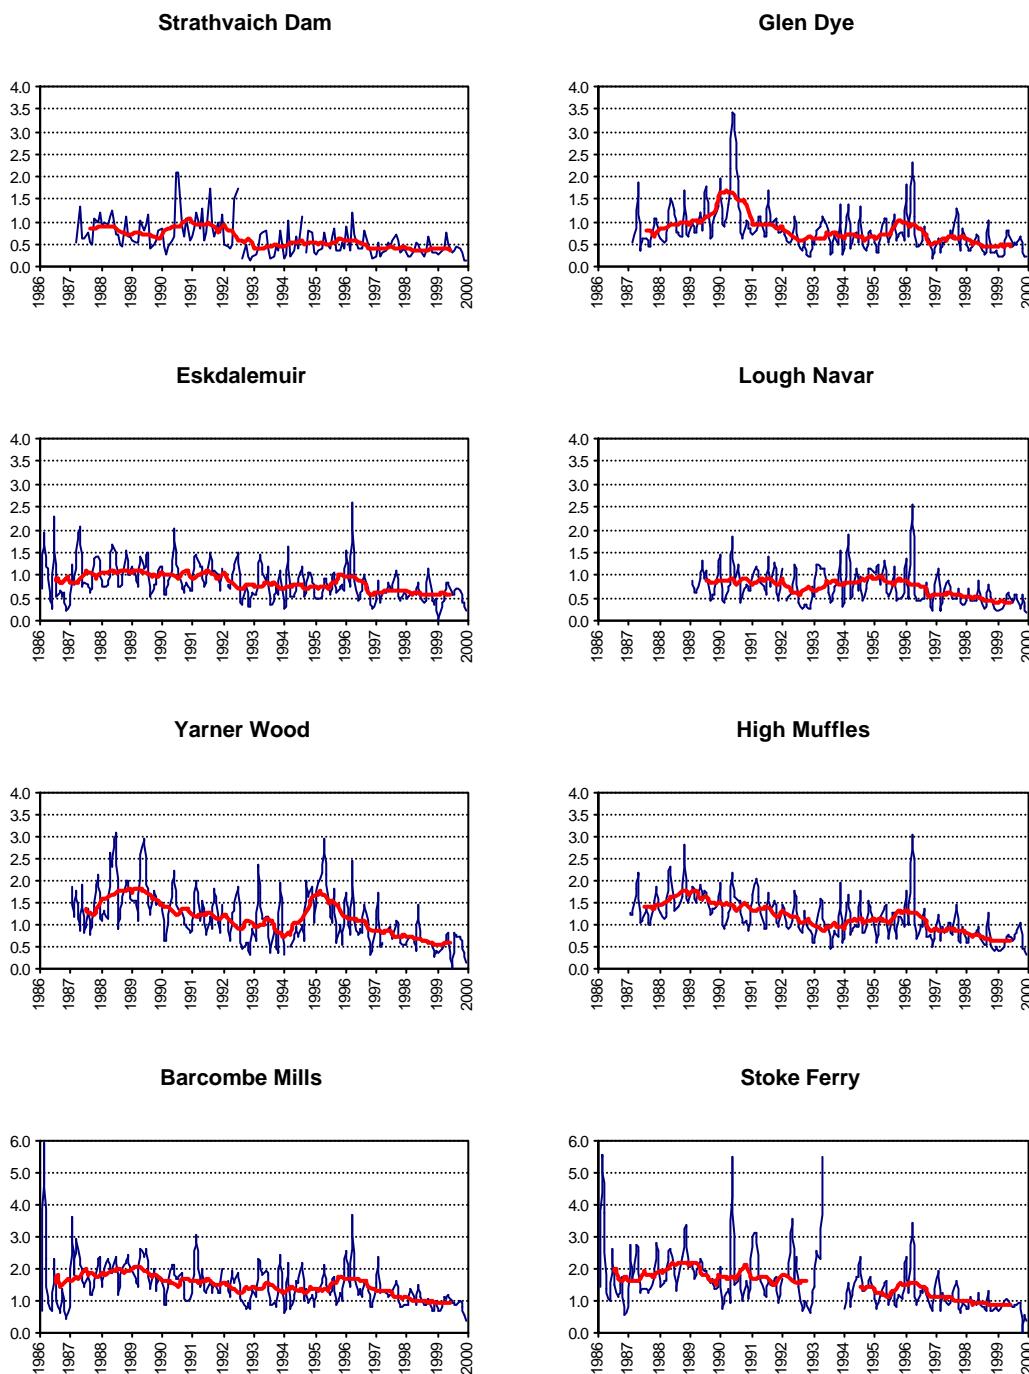

**Figure 3.6: Monthly and Running Annual Mean Concentrations of Sulphur Dioxide at the Daily Sites, 1986 to 1999 ( $\mu\text{g S m}^{-3}$ ).**

At the low concentrations now observed at some sites, only very careful quality assurance and control of sampling can deliver valid data.

### 3.3.3 Trends in Particulate Sulphate

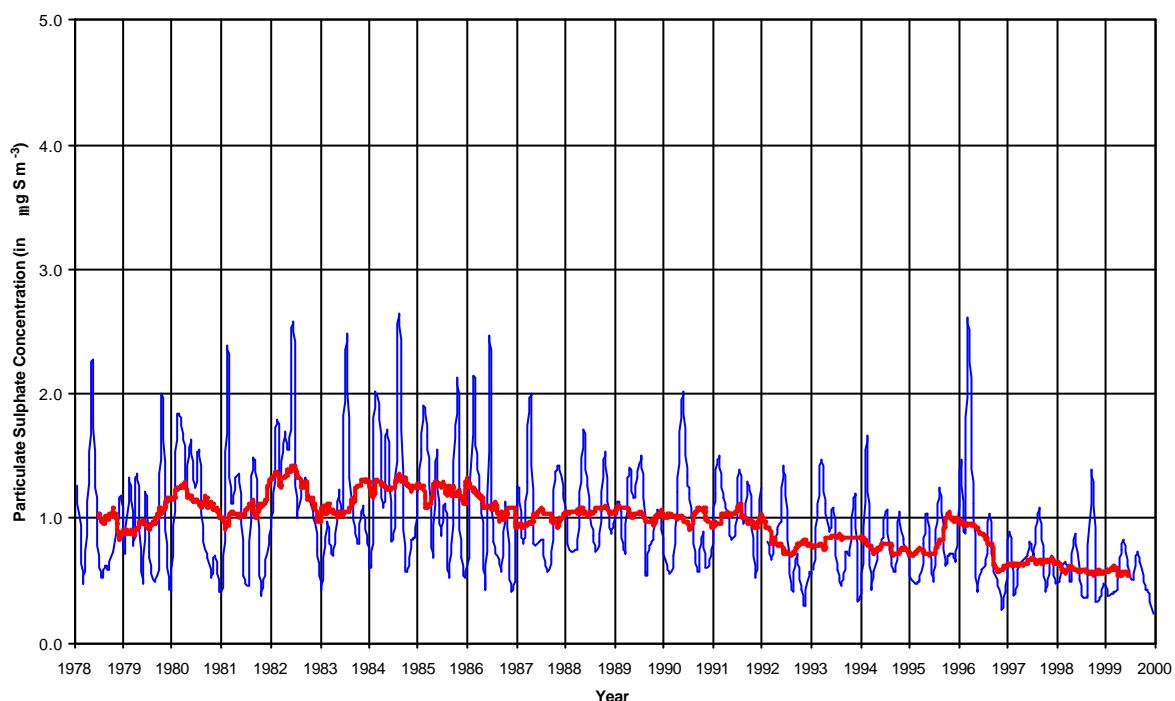

Sulphate concentrations do not obviously exhibit the same degree of decrease as that observed for sulphur dioxide, as shown in Figure 3.7.

**Figure 3.7: Monthly and Running Annual Mean Concentrations of Particulate Sulphate at the Daily Sites, 1986 to 1999 ( $\text{mg S m}^{-3}$ ).**

The highest concentrations were observed at Stoke Ferry and Barcombe Mills for the first half of the sampling period - since that time concentrations at both sites decreased by about 25%. The lowest concentrations were consistently measured at Strathvaich Dam.

Figure 3.8 provides the corresponding monthly mean and running annual mean concentrations of particulate sulphate at Eskdalemuir. The decrease in the concentration of particulate sulphate is much less marked than that of sulphur dioxide. There is more variation around the running annual mean and there is an apparent increase in concentration from 1978 to 1984 followed by a decrease to 1999. Over the period from 1978 to 1999 the average concentration declined from around  $1 \text{ } \mu\text{g S m}^{-3}$  to about  $0.6 \text{ } \mu\text{g S m}^{-3}$ . The high monthly mean concentration in March 1996, associated with a period of extended easterly flow, was one of the highest over the full time series and illustrates how the month-to-month variation is large relative to the long-term trend.

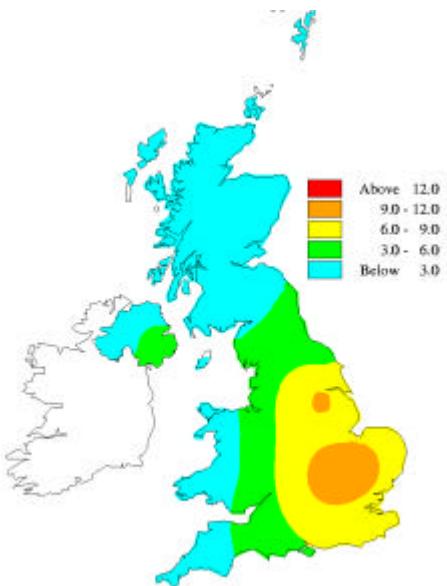

**Figure 3.8: Trends in the particulate sulphate concentration observed at Eskdalemuir since 1978.**

## 3.4 NITROGEN DIOXIDE

### 3.4.1 Concentration Map

The diffusion tube measurements have been used to produce a map of the rural nitrogen dioxide concentrations in the UK for 1999, as shown in Figure 3.9. The map shows that the highest concentrations were observed in the Midlands and southern England. In the main, this reflects the proximity of roads and other aspects of urbanisation to the sampling sites.

The determination of nitrogen dioxide at the rural locations in the acid rain network provides a key input to the mapping of nitrogen dioxide in the United Kingdom [Stedman, 1997].

**Figure 3.9: Interpolated nitrogen dioxide concentrations in 1999 (ppb)**

### 3.4.2 Trends in Nitrogen Dioxide

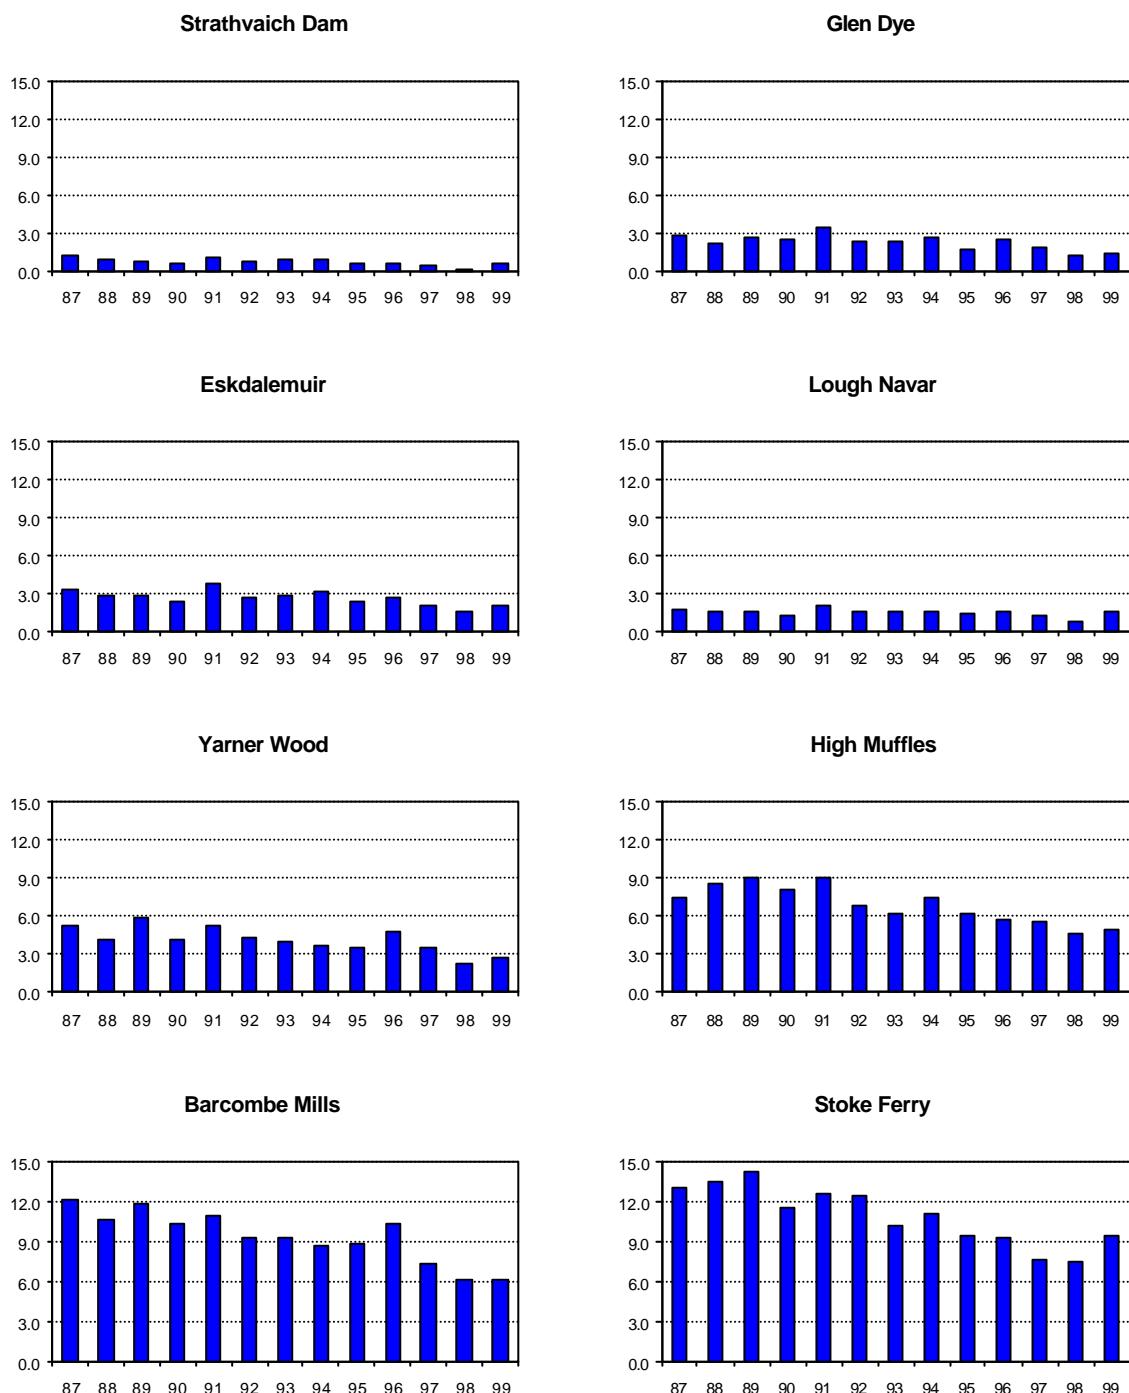

The calculated annual average concentrations for nitrogen dioxide at the measured at 8 sites are presented in Figure 3.10. The annual mean concentrations in 1999 were higher than those measured in 1998. This is consistent with the generally higher concentrations measured for a range of pollutants in 1999. It is likely that the meteorological conditions led to poorer dispersion and dilution of emissions.

UK total emissions of nitrogen oxides have decreased since 1990 with the switch from coal to gas for power generation and the introduction of catalytic converters on petrol-engined vehicles. Given the relatively poor precision of the passive sampler method at low concentrations, the fall in nitrogen dioxide concentrations can only be observed at the relatively high concentration sites such as High Muffles, Stoke Ferry and Barcombe Mills. This is in marked contrast to the lack of a general trend in NO<sub>2</sub> at UK urban diffusion tube monitoring sites where the mean concentration may be limited by availability of atmospheric oxidant rather than nitrogen oxides.

## 3.5 NITRIC ACID

Nitric acid is a key intermediate in the atmospheric oxidation and removal of nitrogen oxides. It is readily adsorbed at plant surfaces and hence rapidly dry deposited. It is highly soluble and hence readily removed by wet deposition. Ambient concentrations are therefore relatively small even though the species makes a significant contribution to the total oxidised nitrogen deposition budget.

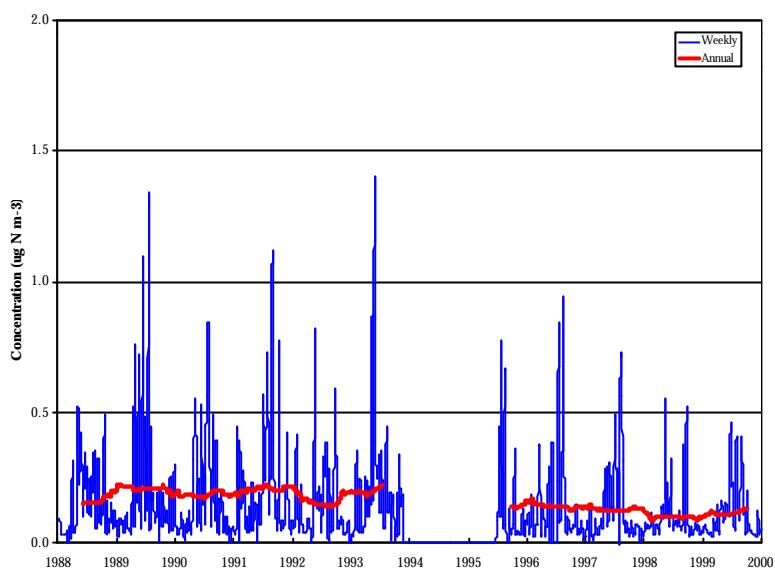

A dual filter technique is used in the UK Acid Deposition Network for nitric acid. The measurement is indicative only. The samples collected under dry summer conditions are likely to under-read as ammonium nitrate may volatilise during sampling. During cool wet winter conditions nitric acid may be absorbed by the front filter.

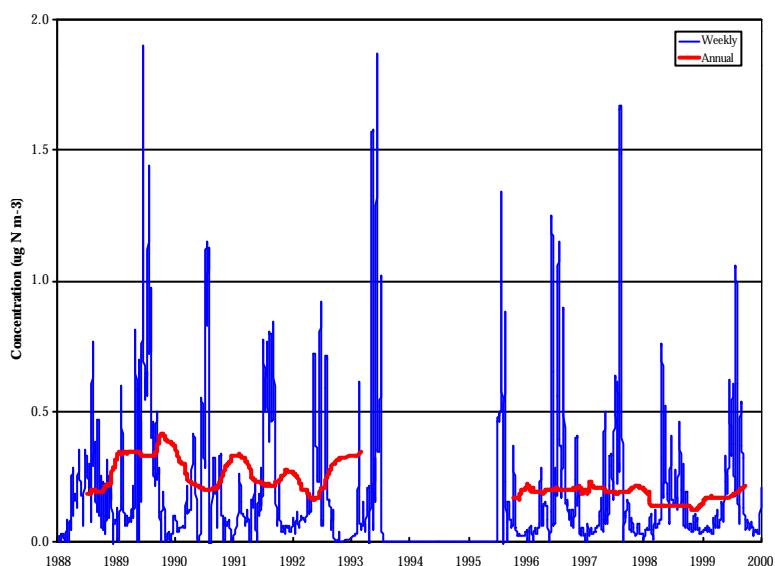

**Figure 3.10: Annual average nitrogen dioxide concentration (ppb).**

The concentrations of nitric acid measured at High Muffles and Stoke Ferry are presented in Figure 3.11 and Figure 3.12. During conditions of elevated ozone concentrations in the summer [Campbell, 1990], the weekly mean concentrations at both sites occasionally reached 1 to 2  $\mu\text{g N m}^{-3}$ . At other times and especially during the winter, nitric acid concentrations were small. The seasonal variation in nitric acid concentrations was therefore much more marked than that in total nitrate, an observation that is probably only partly due to measurement artefacts. Nitric acid is formed largely through the oxidation of  $\text{NO}_2$  by OH, a process that will be faster in summer than in winter because of the increased photochemical activity. Particulate nitrate can

be formed under winter conditions *via* night time oxidation of  $\text{NO}_3$  by ozone and by heterogeneous processes involving  $\text{N}_2\text{O}_5$ .

**Figure 3.11: Weekly and Running Average Concentration of Nitric Acid at High Muffles ( $\mu\text{g N m}^{-3}$ )**

**Figure 3.12: Weekly and Running Average Concentration of Nitric Acid at Stoke Ferry ( $\mu\text{g N m}^{-3}$ )**

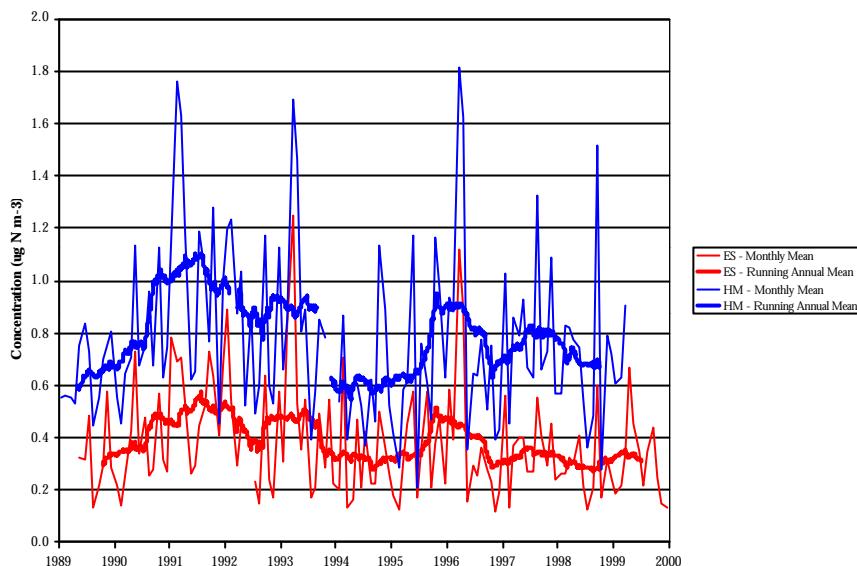

The annual mean concentration measured at High Muffles in 1999 was  $0.11 \mu\text{g N m}^{-3}$ . The concentration of  $\text{HNO}_3$  shows a decrease over the period of the measurements. At Stoke Ferry, the annual mean concentration was higher at  $0.17 \mu\text{g N m}^{-3}$ . Again, the concentration of  $\text{HNO}_3$  has tended to decrease over the period.

### 3.6 TOTAL INORGANIC NITRATE AND AMMONIUM

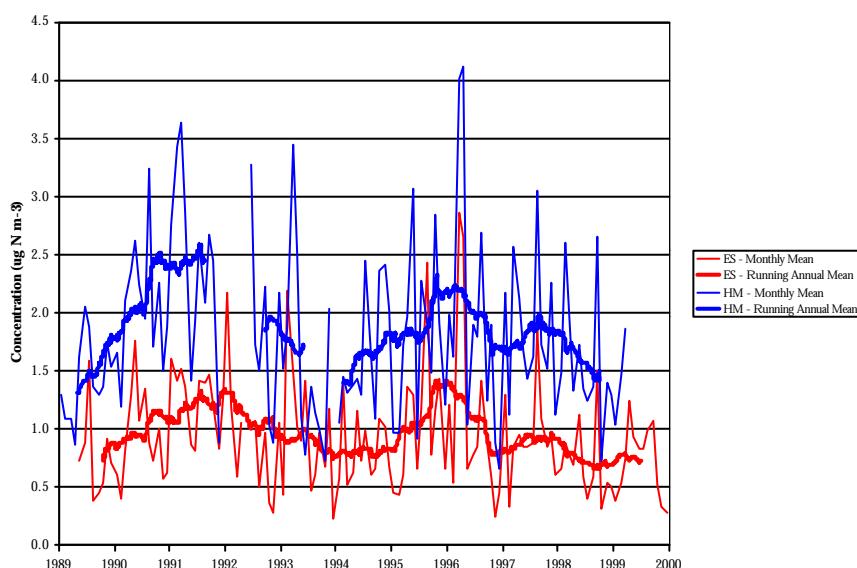

The concentrations of total inorganic nitrate (TIN), taken to be the sum of gaseous nitric acid and particulate nitrate, and of total inorganic ammonium (TIA), taken to be the sum of gaseous ammonia and particulate ammonium, are measured on a daily basis at Eskdalemuir and High Muffles. During 1999, this measurement programme was replaced by separate measurements of the gaseous and particulate phases. The monitoring programme at High Muffles was discontinued on 6<sup>th</sup> April 1999 while that at Eskdalemuir was continue until September 2000 to

provide overlap with the measurements from the new nitric acid monitoring network (Section 4).

The monthly mean concentrations of TIN and TIA measured at Eskdalemuir and High Muffles are presented in Figure 3.13 (TIN) and Figure 3.14 (TIA). Running annual averages are included to remove seasonal effects and to aid the identification of trends.

**Figure 3.13: Monthly Mean and Annual Running Mean Concentrations of Total Inorganic Nitrate ( $\text{mg N m}^{-3}$ )**

**Figure 3.14: Monthly Mean and Annual Running Mean Concentrations of Total Inorganic Ammonium ( $\text{mg N m}^{-3}$ )**

The TIN concentrations measured at High Muffles are approximately twice those measured at Eskdalemuir, similar to the ratio of nitrogen dioxide concentrations. This is consistent with the general trends in pollutant concentrations across the UK. There is no discernible trend in concentration at either site over this period. The influence of meteorology in causing episodes of increased concentration, such as that observed in March 1996, is evident.

As for TIN, the concentrations of total inorganic ammonium measured at High Muffles are approximately twice those measured at Eskdalemuir. There is no significant trend at either site.

## 4. Nitric Acid Monitoring Network

Following the strategic review of the monitoring programme in February 1999, the Department proposed to establish a new network to monitor nitric acid and related species in the UK. The new monitoring network was established during 1999 by the Centre for Ecology and Hydrology at Edinburgh. CEH operate and manage the network under subcontract with the analysis being undertaken by Harwell Scientifics Limited.

### 4.1 OBJECTIVES OF THE NETWORK

The former measurement programme of nitrogen species consisted of sampling total inorganic nitrate and ammonium on a daily basis at 2 sites (Section 2.2.3) and the indicative measurement of nitric acid on a daily basis at 2 sites (Section 2.2.5). These measurements were considered to have limited usefulness since gaseous and aerosol components were not separated, while the effort involved in daily sampling could be better distributed to include less frequent sampling at more sites over the UK. The new network has been established to provide:

- (a) monitoring of  $\text{HNO}_3$  and related species at 12 locations over the UK on a monthly basis. The aim of these measurements is to explore spatial patterns, compare results with dispersion models, seasonality and contribute to national nitrogen deposition estimates.
- (b) monitoring of  $\text{HNO}_3$  and related species at 1 site in a high  $\text{HNO}_3$  concentration area of south east England on a daily basis. The aim of these measurements is to explore the dynamics of  $\text{HNO}_3$  formation and concentrations in relation to other photochemical pollutants in order to improve the process based atmospheric chemistry and dispersion models. The effect of these changes should be seen in validation and improvement of the models in comparison with the observed occurrence of pollution episodes.

### 4.2 METHODS, SITES AND DATA COLLECTION

A map of the monthly  $\text{HNO}_3$  monitoring network is shown in Figure 4.1. Nitric acid and related species are monitored on a monthly basis at 12 locations, and daily measurements are carried out at Barcombe Mills in East Sussex.

#### Monthly Sampling

The monthly monitoring has been implemented using the CEH DELTA (DEnuder for Long-Term Atmospheric sampling) system in an integrated fashion with the UK Ammonia Monitoring Network. Sampling commenced in September 1999.

The sampling train used in the CEH DELTA system is shown Figure 4.2.  $\text{HNO}_3$ ,  $\text{SO}_2$  and  $\text{HCl}$  are removed by the first set of  $\text{K}_2\text{CO}_3$ / glycerol coated denuders, and a second set of citric acid coated denuders removes  $\text{NH}_3$ . Two sets of filter packs at the end of the sampling train removes the aerosol components -  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$  and  $\text{NH}_4^+$ . Extracted aqueous samples from

**Figure 4.1: Map of 12 monitoring sites for  $\text{HNO}_3$ ,  $\text{NO}_3^-$  and related acid gas/particle measurements.**

#### Daily Sampling

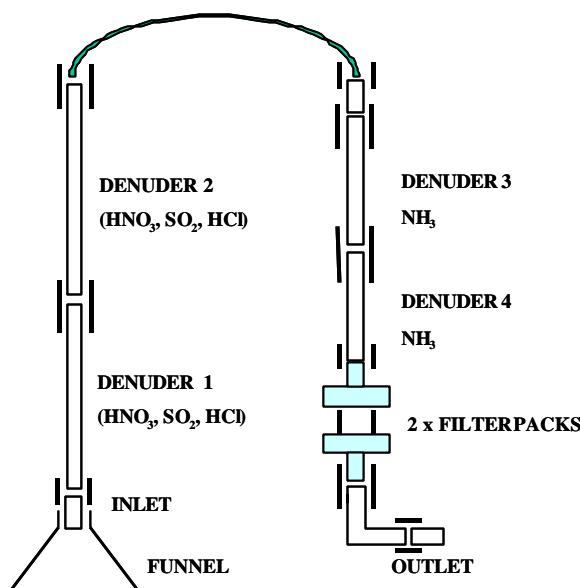

A new annular denuder system was established for the daily measurements. The Chemspect<sup>TM</sup> model 2500 air sampling system was installed at the Barcombe Mill site in February 2000 and daily measurements commenced in April 2000.

### 4.3 NITRIC ACID NETWORK MEASUREMENTS

#### 4.3.1 Monthly measurements

The monthly measurements have proved successful and have now been running since September 1999. The smooth running has partly been due to the use of the ammonia network sites which were already established with reliable site operators. Using the DELTA sampler also builds on the established approach used for ammonia. The quality control using a double denuder systems confirms that the capture efficiency in the denuders is adequate and that little correction is needed for unsampled gases.

Graphs of the concentrations of  $\text{HNO}_3$  and  $\text{NO}_3^-$  at each site are shown in Figure 4.3. The graphs illustrate that concentrations of both species are reasonably stable at a monthly level, and

**Figure 4.2: Sampling train for monthly air measurements.**

the denuders and filter packs are sent to Harwell Scientifics Ltd for chemical analysis on a monthly basis. Denuder sample extracts are analysed for  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$  and  $\text{Cl}^-$  and filter sample extracts are analysed for  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$ ,  $\text{Na}^+$ ,  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$ .

have a weak seasonal variability. Although not apparent at all sites, concentrations of  $\text{HNO}_3$  are often seen to be highest in summer (e.g. linked to photochemical activity), while concentrations of nitrate were largest in Spring 2000.

Although these graphs are shown here to illustrate the trends for  $\text{HNO}_3$  and  $\text{NO}_3^-$ , parallel measurements have been made for  $\text{HCl}$  and  $\text{Cl}^-$ ,  $\text{SO}_2$  and  $\text{SO}_4^{2-}$ , as well as base cations. The results from the other measurements are illustrated by scatter plots of the concentrations between gas and aerosol phases of the different components (Figure 4.4).

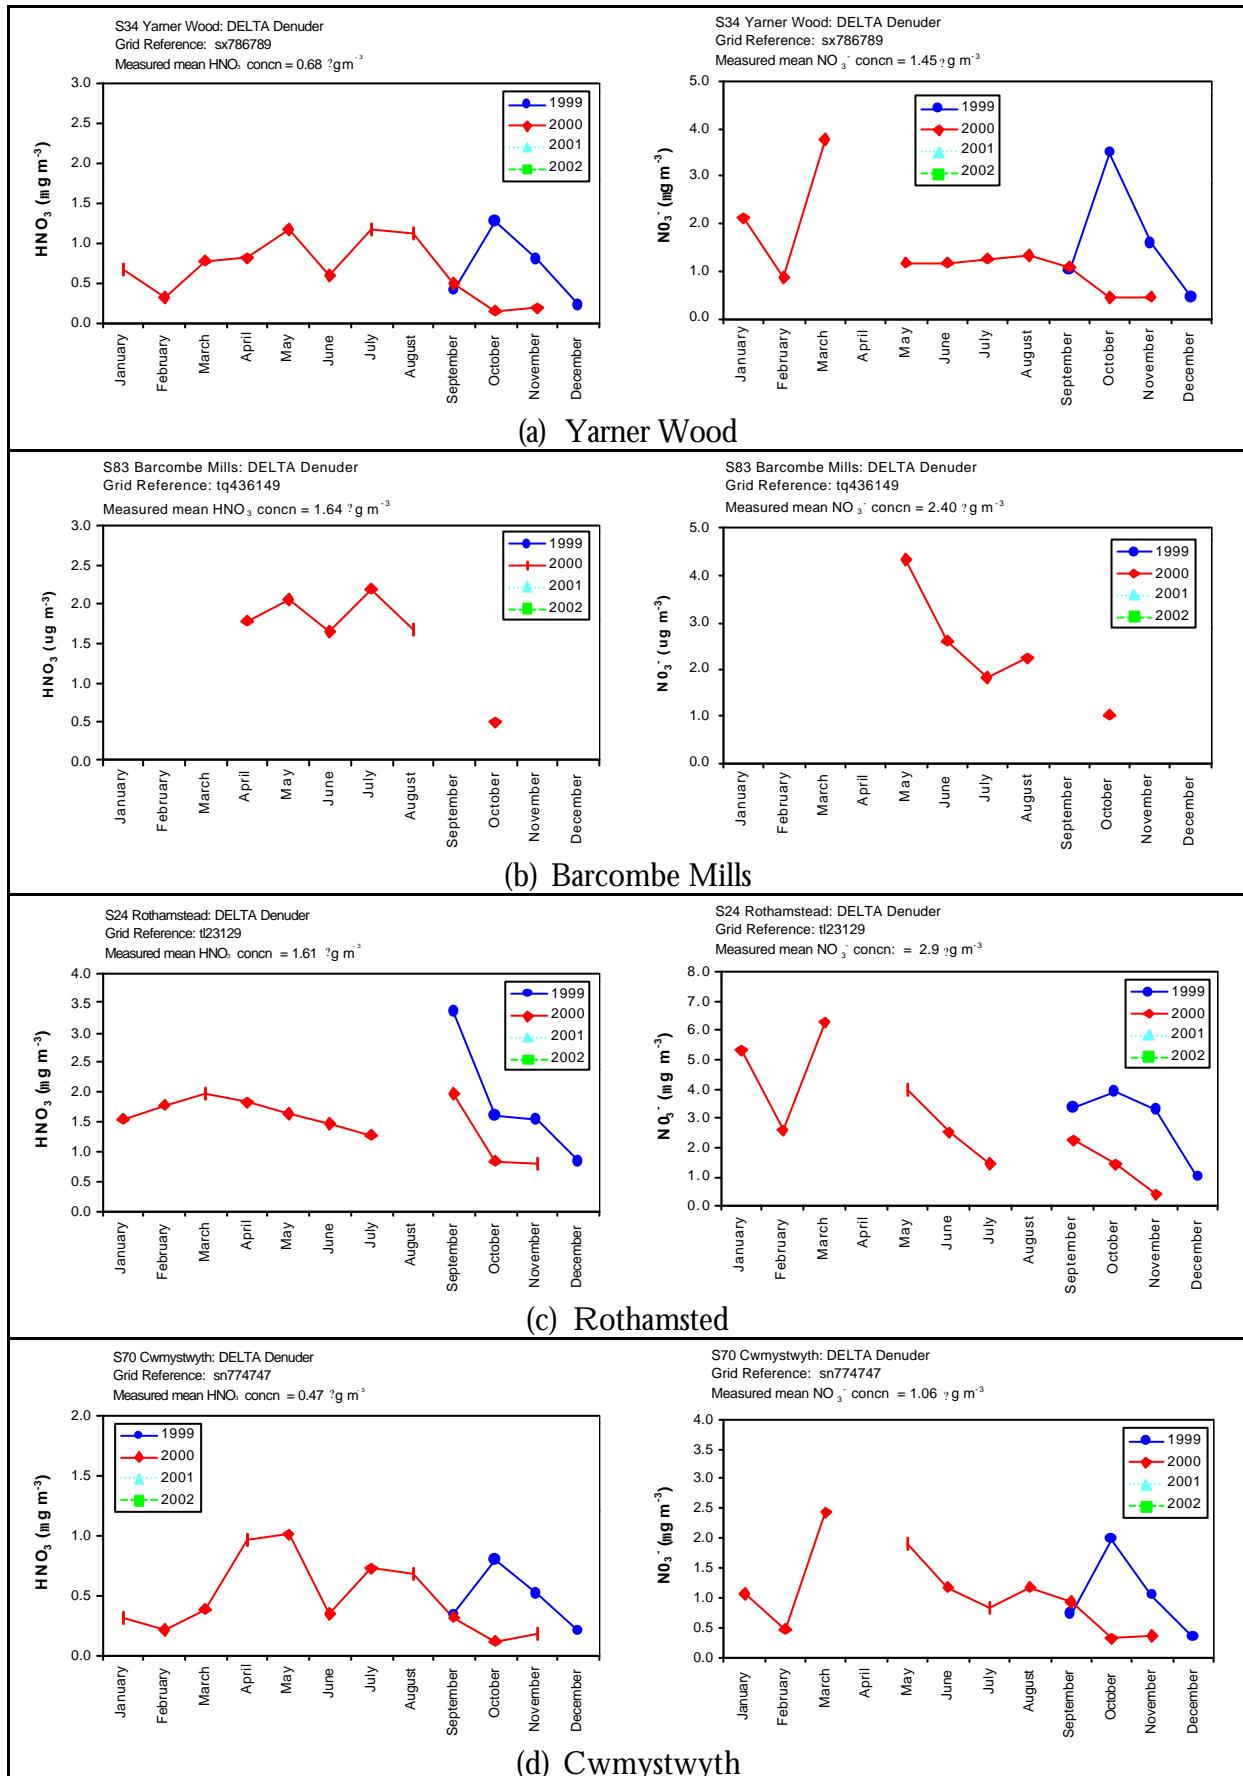

There is some correlation between the concentrations of all the pollutants, and much of this may be related to correlation in the emission distribution of precursor gases or the effect of long range transport of aerosol across the UK and from Europe. The comparison of the gas phase concentrations shows that there is more  $\text{NH}_3$  than either  $\text{SO}_2$  or  $\text{HNO}_3$  at these sites (on molar basis), while  $\text{SO}_2$  is in excess over  $\text{HNO}_3$ . The correlations are highest for the aerosol components. This reflects the longer residence time of these measurements leading to more representative sampling as well as the close coupling between acidic and basic aerosol components. As with the gases, reduced nitrogen ( $\text{NH}_4^+$ ) is in molar excess over  $\text{SO}_4^{2-}$  and  $\text{NO}_3^-$ . However, for aerosol  $\text{NO}_3^-$  is in molar excess over  $\text{SO}_4^{2-}$  and they are about equal in terms of equivalents of  $\text{H}^+$ .

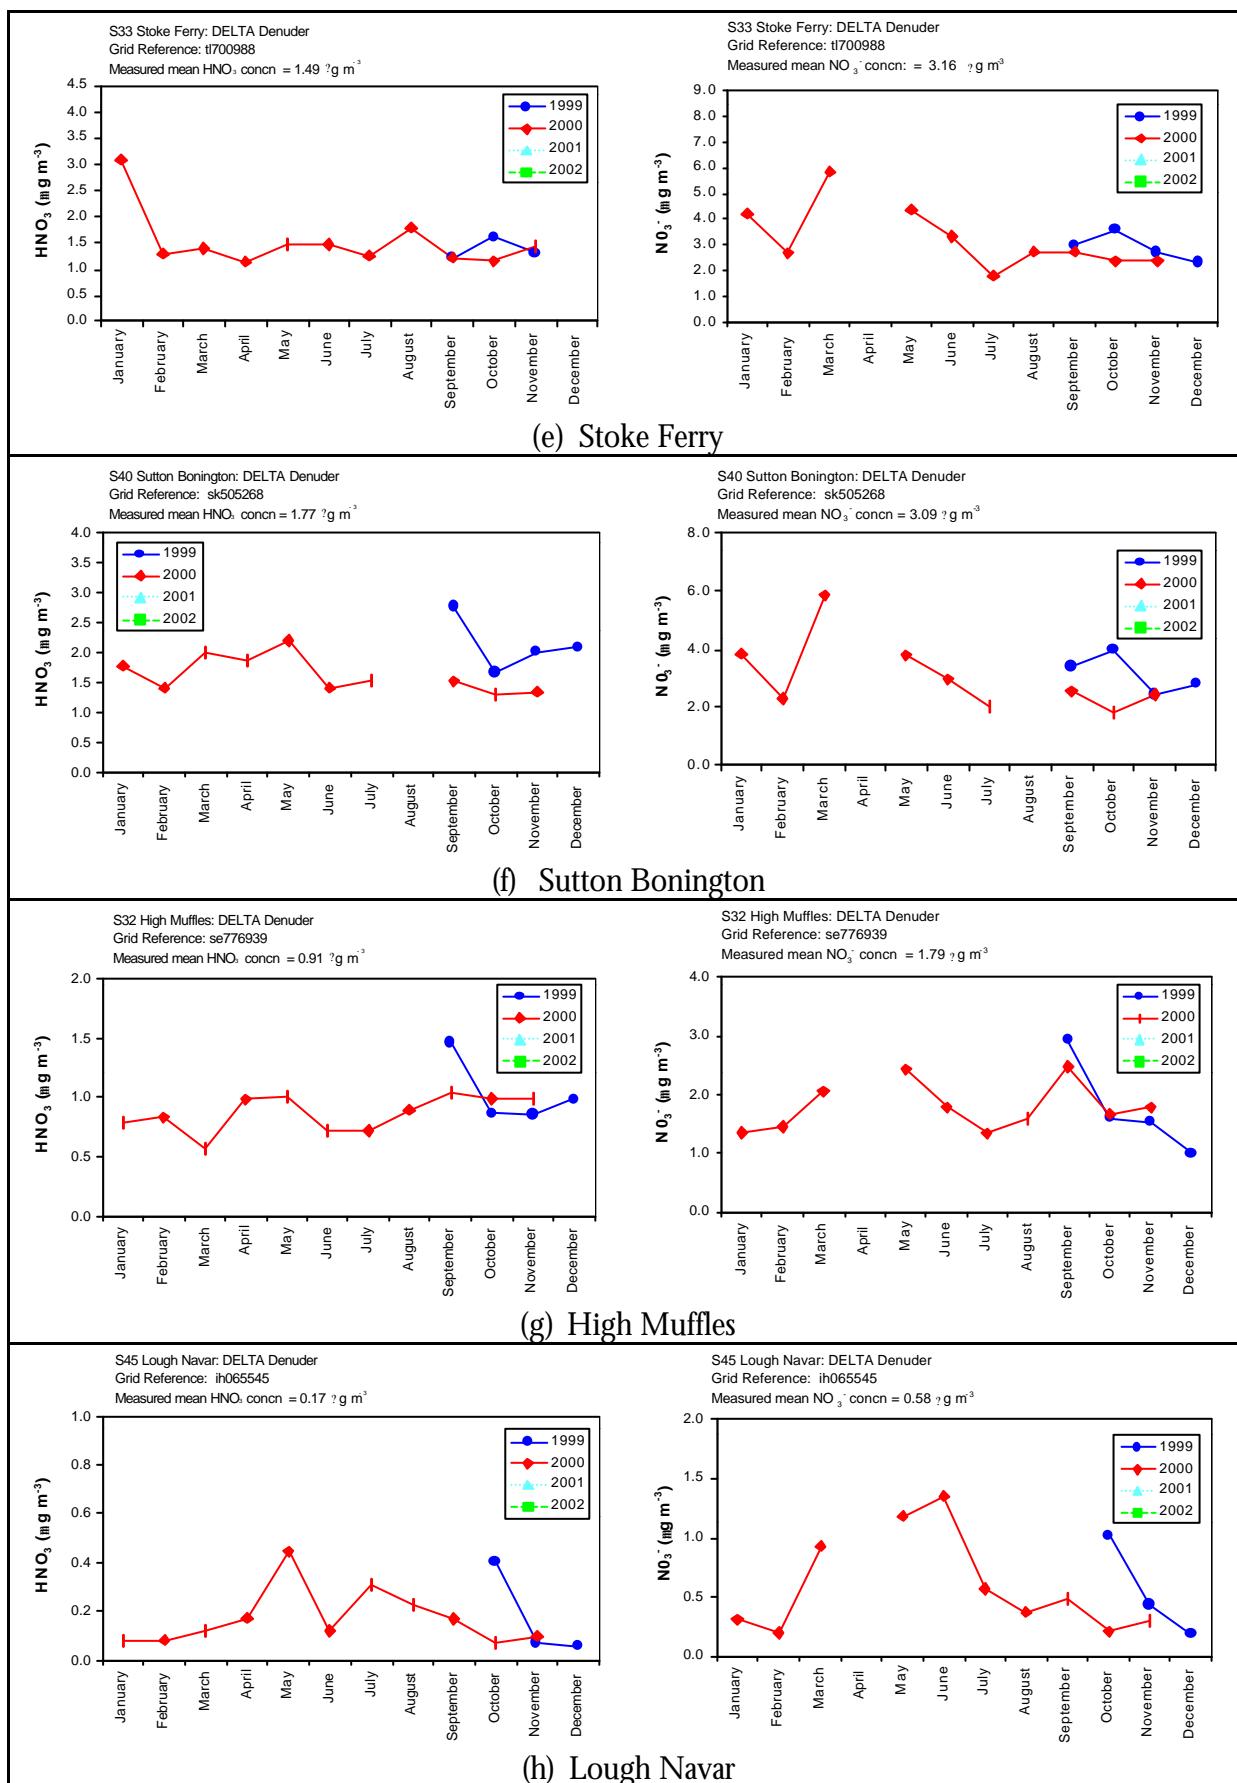

The good correlations between these species also indicate the quality of the measurements, since uncertainty in the measurements on a monthly basis would propagate through to scatter in these plots.

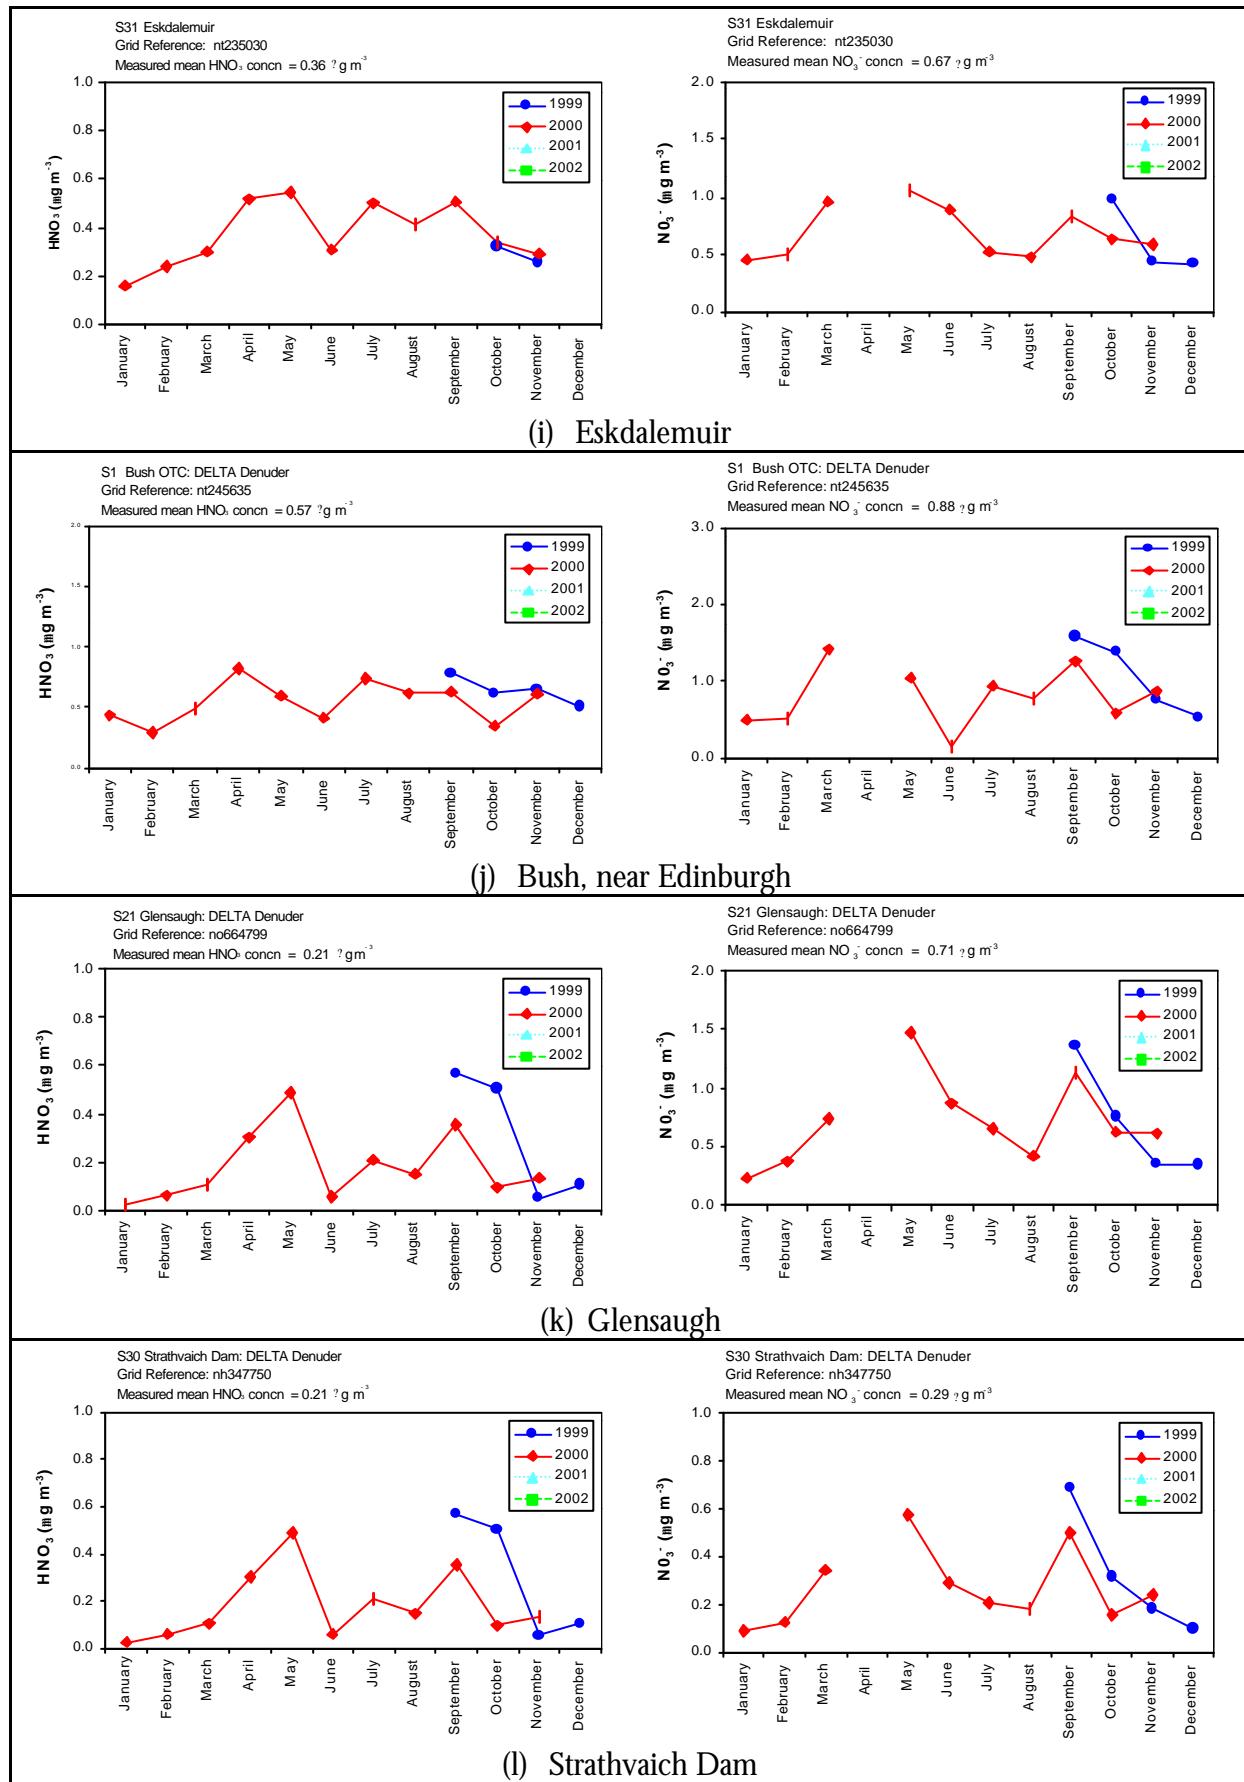

The following 3 pages contain Figure 4.3:

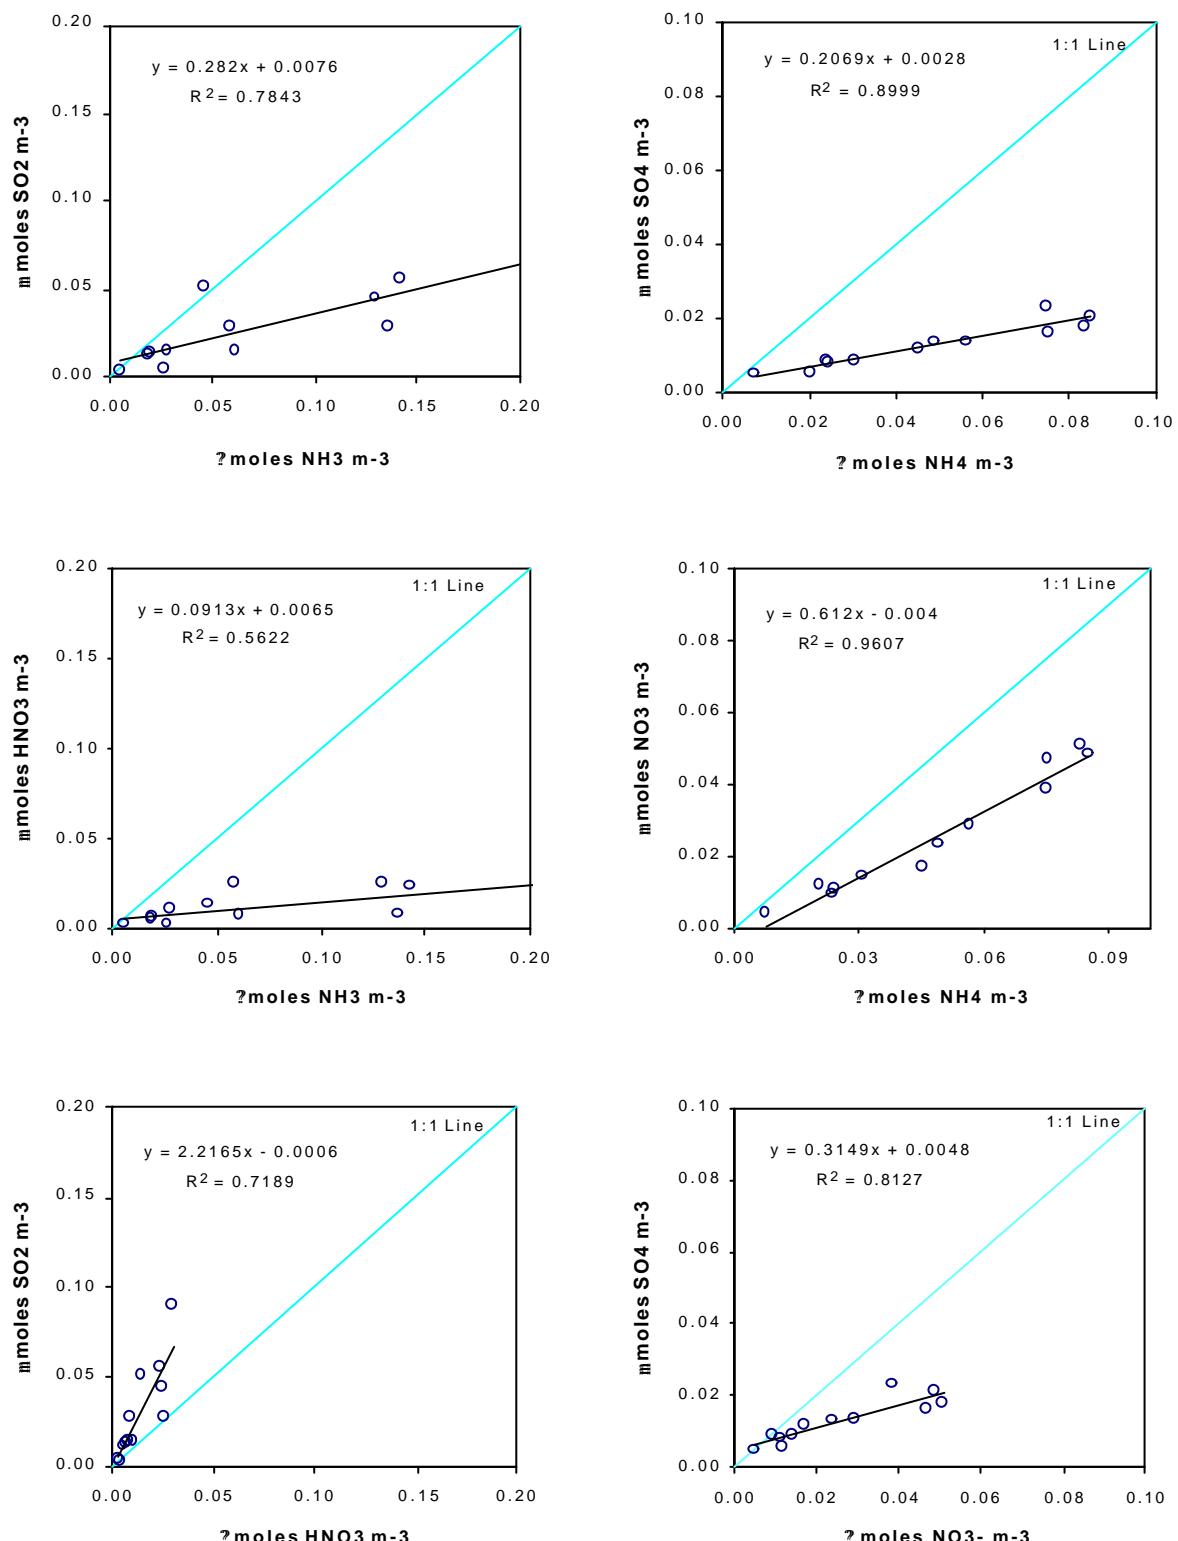

**Figure 4.3: Measurements of Gaseous  $\text{HNO}_3$  and aerosol  $\text{NO}_3^-$  made at the 12 Sites in the Nitric Acid Monitoring Network between September 1999 and November 2000.**

(k) Glensaugh	(l) Strathvaich Dam

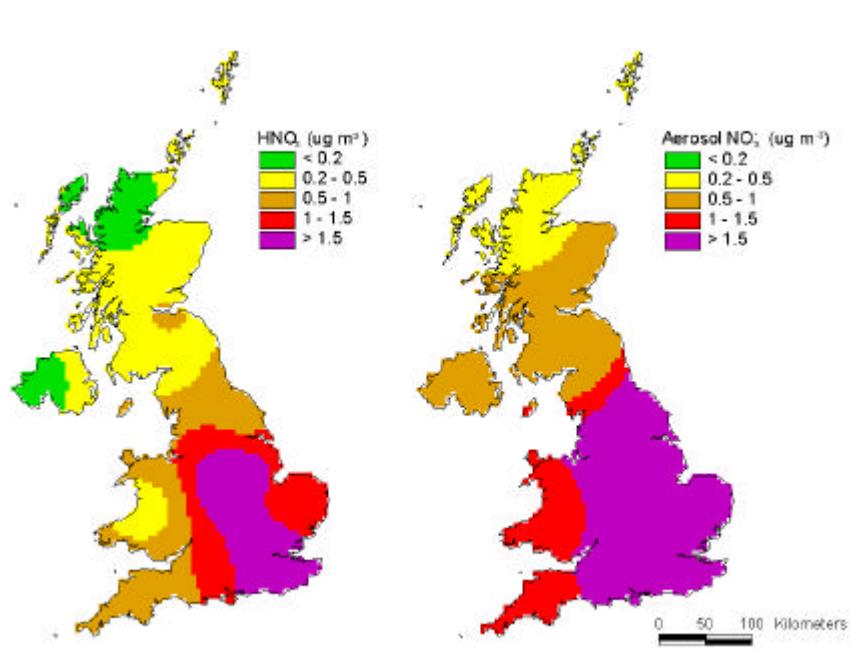

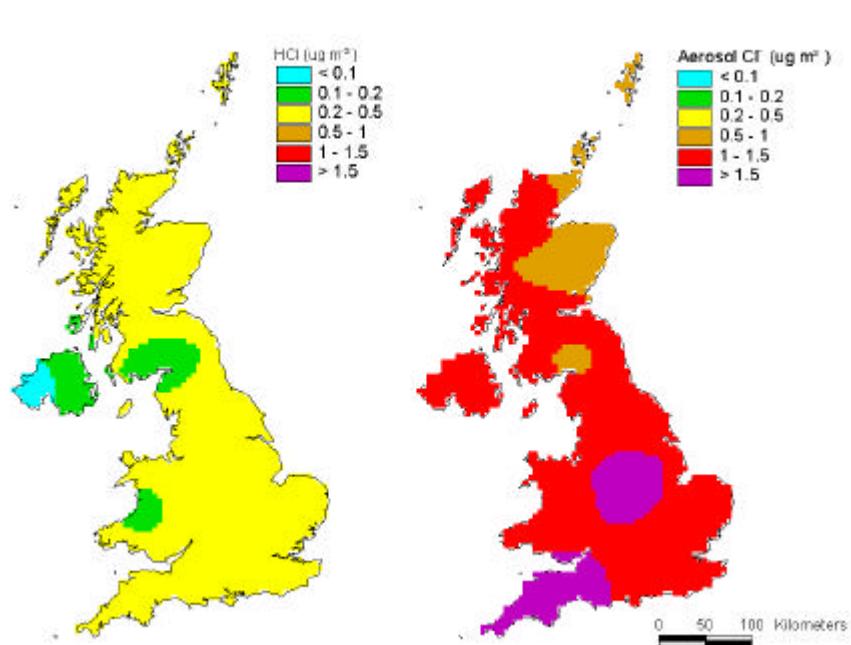

**Figure 4.4:** Scatter plots of showing the relationships between concentrations of  $HNO_3$ ,  $SO_2$ ,  $NO_3^-$ , and  $SO_4^{2-}$  from the monthly measurements at 12 sites (units:  $\text{mmol m}^{-3}$ ).

Of major importance from the 12 site monthly network is the estimation of the concentration field across the UK. Illustrative maps for  $\text{HNO}_3$  and HCl are shown in Figure 4.5 and Figure 4.6. The spatial distributions of  $\text{HNO}_3$  and  $\text{NO}_3^-$  are seen to be rather different to that of HCl and  $\text{Cl}^-$ . Both the nitrogen species are largest in central and south east England, with the lowest concentrations of  $\text{HNO}_3$  in Scotland and Northern Ireland.  $\text{HNO}_3$  is seen to be more spatially variable than  $\text{NO}_3^-$  aerosol, reflecting the long atmospheric residence time of the latter.

**Figure 4.5: Spatial pattern of  $\text{HNO}_3$  and aerosol  $\text{NO}_3^-$  concentrations in the UK from monthly measurements (Sept 1999-Nov 2000).**

**Figure 4.6: Spatial pattern of HCl and aerosol  $\text{Cl}^-$  concentrations in the UK from monthly measurements (Sept 1999-Nov 2000).**

Although not so clearly seen in Figure 4.6, (in order to show concentrations on the same scales), HCl concentrations are largest in the south east of England (Stoke Ferry, Rothamsted) and lowest in the west of the country (Lough Navar, Eskdalemuir and Cwmystwyth). In contrast the highest concentrations of Cl<sup>-</sup> are at Sutton Bonington and Yarner Wood. This difference in distribution may reflect the dual contribution to atmospheric Cl<sup>-</sup> anthropogenic and marine sources. With highest HCl concentrations in the south east, this is presumably largely product of emission or reaction with HNO<sub>3</sub> to produce HCl. In contrast, the larger concentration of Cl<sup>-</sup> in the south west probably reflects a marine contribution to the aerosol.

#### **4.3.2 Daily measurements**

The daily sampling system for HNO<sub>3</sub>, particulate NO<sub>3</sub><sup>-</sup> and other species has proved to be more involved and troublesome than the monthly measurements. Establishing the supply and receipt of the annular denuders (4 suitcases representing £5k of glassware every two weeks) was a major task and all the initial problems have mostly been overcome (with so far only one occurrence of breakage). More difficult has been the reliable operation of the Chemspect system, which has seen a large number of sampling problems, leading to substantial down time. The suppliers of this equipment (which is highly rated internationally) continue to be called out (under warranty) by CEH to fix the equipment. With perseverance, it is expected that these problems will be ironed out.

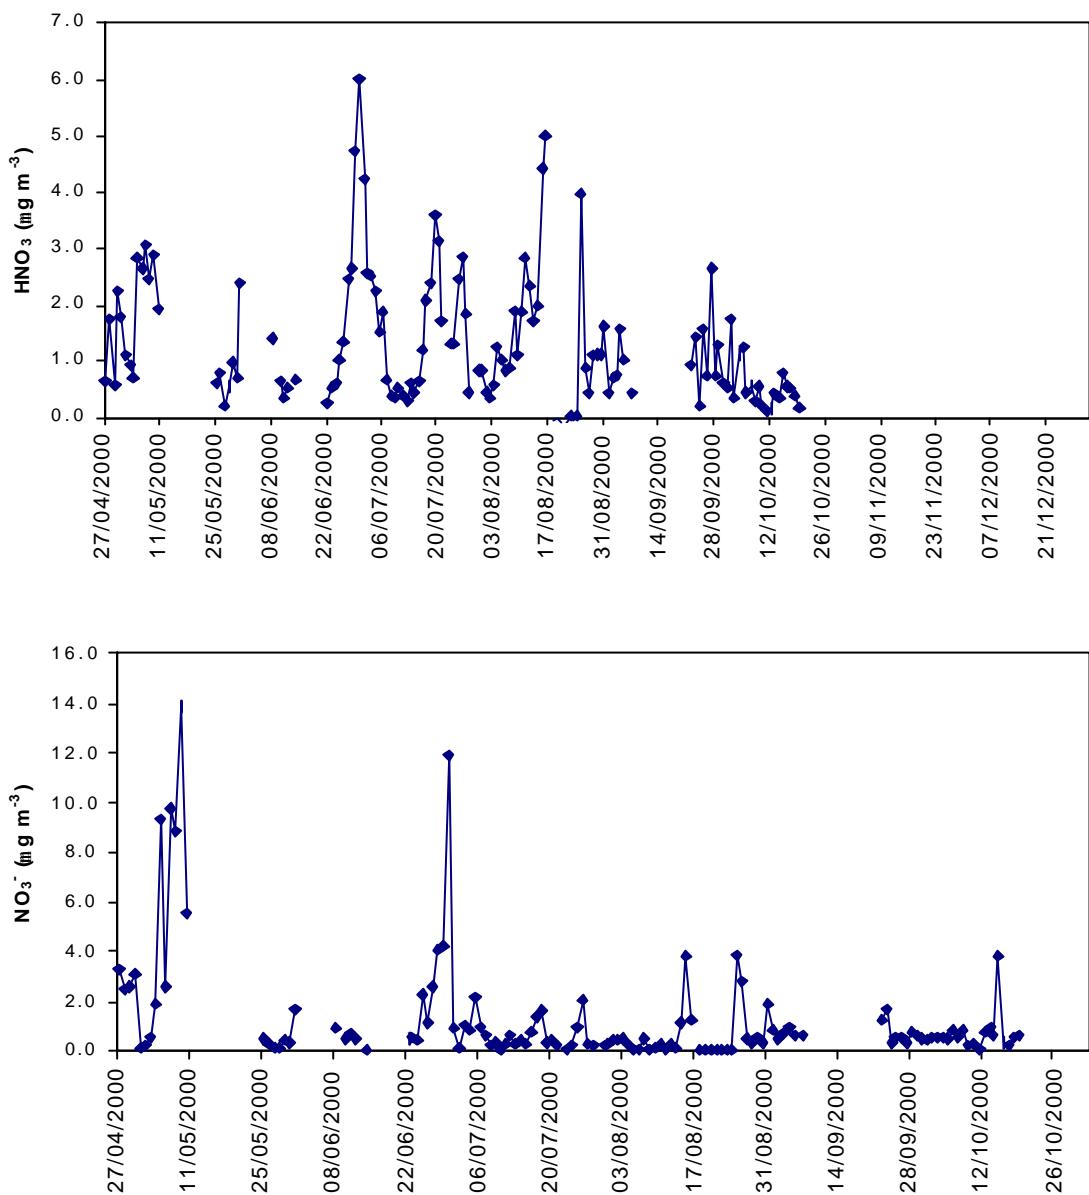

Nevertheless, despite these problems, this system has produced a substantial data series of daily concentrations. Example results are given in Figure 4.7 which show HNO<sub>3</sub> and nitrate concentrations for several months during 2000. The results illustrate the high temporal structure of these pollutants. The variation in HNO<sub>3</sub> reflects a close linkage to production in photochemical episodes as well as a relatively short lifetime before it is removed either by dry deposition or conversion to aerosol NO<sub>3</sub><sup>-</sup>.

### **4.4 SUMMARY AND NEXT STEPS**

The new nitric acid monitoring network has been established for over a year. Valuable new data have been produced on the behaviour of gaseous and aerosol species involved in transboundary and urban air pollution.

The major challenge at present is to improve the reliability of the daily Chemspect system, and particular pressure is being placed on the supplier to fix problems such as temperature control, the performance of the inlet flaps. By contrast the monthly network is operating very smoothly, and providing a record with very few missing points.

Apart from the continued operation of the network, efforts over the next months will focus on quality assurance and the preparation of definitive datasets. These datasets will then be available for use on other DETR contracts (*e.g.*, mapping dry deposition, studying the evolution of nitric acid and nitrate in photochemical episodes).

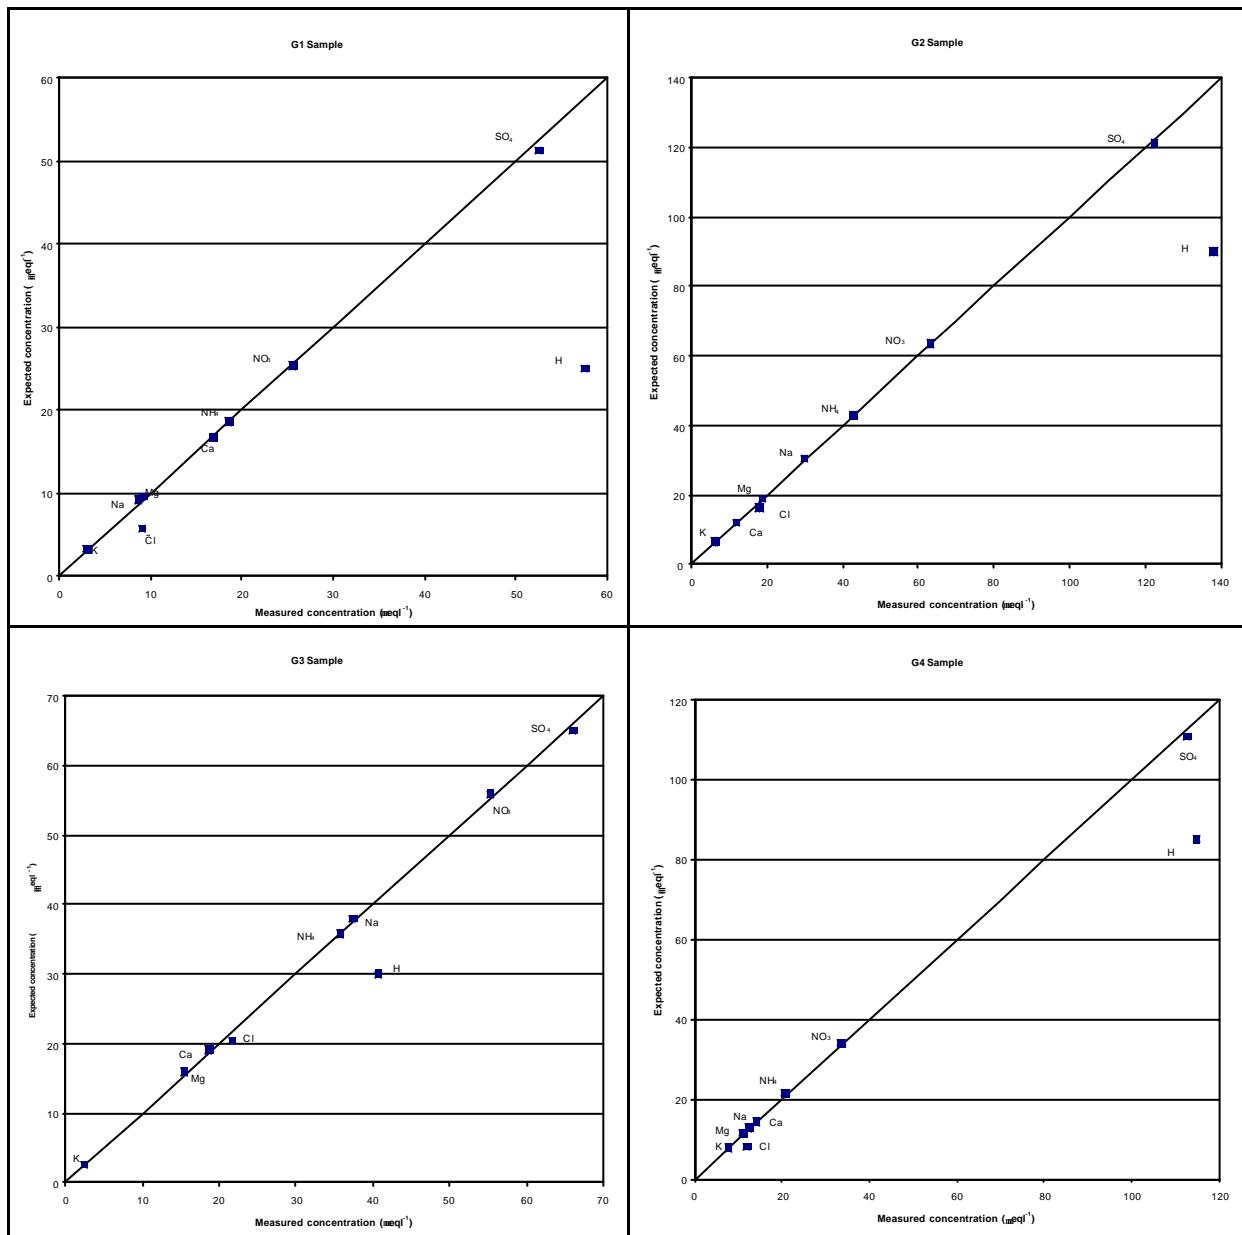

**Figure 4.7: Record of daily concentrations of  $\text{HNO}_3$  (upper panel) and aerosol  $\text{NO}_3^-$  (lower panel) at Barcombe Mills, Sussex**

# 5. Other Activities

## 5.1 EMEP INTERCOMPARISON

AEA Technology participated in the 18<sup>th</sup> EMEP measurement intercomparison. Figure 5.1 presents a comparison of the ion concentrations determined at AEA Technology and those expected for the four rainwater samples G1 to G4.

**Figure 5.1: Expected and Measured Ion Concentrations for the EMEP Intercomparison**

Apart from the hydrogen ion concentrations, the measured ion concentrations were in excellent agreement with the expected concentrations for all four samples. The hydrogen ion concentration is measured using a pH probe while the other ions were all measured using the new ion chromatographs. The discrepancy on the hydrogen ion measurements is being checked. It is however clear that the performance of the new ion chromatographs is very good. In the previous intercomparison, the largest differences were noted for magnesium and calcium. In the present intercomparison, the differences are now comparable to those of the other ions.

## **Notes to Appendix 1**

There are two pages of information for each site. The first includes site characteristics, time and seasonal trends; the second page presents individual concentrations for all samples collected (including those samples contaminated with bird strike). Also included are the Ordnance Survey co-ordinates, latitude and longitude and altitude of the site and the average rainfall for the 5 x 5 km square containing the site for the years 1941 to 1970.

Abbreviations for monitoring equipment, which also includes co-located sampling instrumentation, are given below:

- WOC              Wet-only collector for daily measurement of rainfall composition
- DT                Monthly diffusion tube. Measurement for nitrogen dioxide
- Daily SO<sub>2</sub>      Daily measurements of SO<sub>2</sub> by hydrogen peroxide bubbler and of particulate sulphate on a Whatman 40 filter with ion chromatographic analysis
- Weekly SO<sub>2</sub>     Weekly measurements of SO<sub>2</sub> by hydrogen peroxide bubbler with ion chromatographic analysis
- TIN               Daily measurements of total inorganic nitrate using a filter pack
- TIA               Daily measurements of total inorganic ammonium using a filter pack
- ozone             Hourly measurements surface ozone
- SO<sub>2</sub>              Hourly measurements of SO<sub>2</sub>
- NO<sub>x</sub>             Hourly measurements of NO<sub>x</sub>
- WF                Weekly measurements of nitric acid and nitrate, sulphate, ammonium, sodium and chloride particles using a filter pack
- Met               Meteorological measurements.
- UKAWMN          Catchment monitored by the UK Acid Waters Monitoring Network.
- EMEP             Daily data from this site are made available to EMEP

In the tables of data, a '-' indicates a missing value. A dry week is indicated by a complete row of '-'s. Some weeks only have rainfall volumes reported; this is because no analyses were carried out on very low volume rainfall samples or on samples that were visibly contaminated. Individual ion concentrations or conductivities are missing for some low volume weeks, due to there being insufficient sample for complete analysis. A '< Value' indicates that the concentration was less than the detection limit of the analysis. Annual precipitation-weighted mean concentrations and rainfall total are included at the bottom of the table.

A phosphate concentration was also determined for each rainwater sample. A phosphate concentration > 0.1 mg P l<sup>-1</sup> (or > 9.7 µeq l<sup>-1</sup>) was taken as evidence of contamination by birds. Although all these samples have been included in the tables, they were not included in the calculation of annual means. The rainfall totals presented in Appendix 2, Table 10 include all samples collected and are therefore sometimes higher than the totals presented in this section.

**NOTE - In Issue 1 of the report, the sample collected on 23/4/99 was shown to have a pH of 3 and ion concentrations were given. This sample has subsequently been shown to have had acid added and hence has been excluded from the above table. The precipitation-weighted hydrogen ion concentration has been revised down from 32  $\text{meq l}^{-1}$  to the value shown (12  $\text{meq l}^{-1}$ ).**

long-term trends in concentration $(+x = \text{increase}; -x = \text{decrease})$	
hydrogen ion	-1.75 ueq/l (-3.69 %/year): 14 years' data ++ Moderately strong trend detected
non-marine Sulphate	-2.71 ueq/l (-3.35 %/year): 14 years' data ++ Moderately strong trend detected
Nitrate	-0.24 ueq/l (-0.52 %/year): 14 years' data - No significant trend detected
ammonium	-1.06 ueq/l (-1.70 %/year): 14 years' data - No significant trend detected

## **Geostatistics**

---

## GEOSTATISTICS

The use of geostatistics in the analysis of United Kingdom precipitation composition was described by Webster *et al.* (1991). A brief discussion is reproduced here. In a geostatistical treatment of spatial variability the concentration of an ion in precipitation, averaged over a time period of one year, is treated as a regionalised random variable. It is assumed that the values at the sites are drawn from the distribution of a random variable with a constant mean. The variance, however, depends on the separation of the sites. For example, within one 20 km x 20 km grid square the variance would probably be smaller than within a 200 km x 200 km square. The dependence of the variance on separation (usually termed the lag) is described by a quantity known as the semi-variance:

$$\gamma(h) = \frac{\sum(z_1 - z_2)^2}{2n} \quad 1$$

Where there are n pairs of data  $z_1, z_2$  separated by a distance h. A plot of the semi-variance against lag is called a **variogram**.

It can be shown that the variogram function (usually termed the variogram model) must be selected from one of a few allowed forms, each of which has one or more variable parameters which must be fitted to the experimental data. Models that are allowed are:

### Exponential

$$\gamma(h) = c_0 + c_1 (1 - e^{-h/a}) \quad 2$$

### Spherical

$$\gamma(h) = c_0 + \frac{c_1}{2} \left\{ \frac{3h}{a} - \left( \frac{h}{a} \right)^3 \right\} \quad 3$$

### Linear

$$\gamma(h) = c_0 + \omega h^\theta \quad 4$$

The parameter  $c_0$ , known as the “nugget”, is the residual variance for collocated measurements and is a result of measurement error or variability on a scale smaller than the separation of the measurement sites. The “range”, a, is a measure of the separation beyond which the measurements are uncorrelated, and the “sill”,  $c_0+c_1$ , is the maximum semi-variance. The linear model applies when the regionalised varia has an unlimited capacity for spatial dispersion. There is no sill and the parameter  $\omega$  is called the factor and  $\theta$  the exponent.

Once a variogram model has been found it can be used in an interpolation procedure known as kriging to produce contour maps from irregularly spaced data. In the kriging process the interpolated value is expressed as a linear combination of the measured data  $l_1 z_1 + l_2 z_2 + \dots$ . Using the variogram model the variance of the interpolated estimate can be expressed in terms of the  $l_i$  and this variance is then minimised subject to the constraint that the  $l_i$  sum to 1. The result

is the best unbiased linear estimate in that it has the smallest error in the statistical sense. A further advantage of using kriging is that the interpolation variance is known for each interpolated estimate and this can be mapped along with the concentration to provide a measure of the reliability of the map.

The models fitted to the experimental points in the variogram for  $\log_e$  [acidity], non-marine sulphate, nitrate and ammonium are listed in Table A.3.1.

**Table A.3.1** - Variogram Models fitted to 1999 Annual Mean Concentrations of the Major Ions

Ion	Model	Sill ( $\mu\text{eq l}^{-1}$ ) <sup>2</sup>	Range (km)
acidity ( $\log_e$ transformed)	exponential	0.45	260
non-marine sulphate	exponential	400	300
nitrate	exponential	200	260
ammonium	exponential	400	260
